Manasi Kumari Sahukar and Gopal Krishna Panda

Diophantine equations with balancing-like sequences associated to
Brocard-Ramanujan-type problem

Accepted manuscript

This is a preliminary PDF of the author-produced manuscript that has been peer-reviewed and accepted for publication. It has not been copyedited, proofread, or finalized by Glasnik Production staff.
1. Introduction

A positive integer $B$ is a balancing number [1] if $1 + 2 + \cdots + (B - 1) = (B + 1) + \cdots + (B + R)$ holds for some positive integer $R$. If $B$ is a balancing number, then $8B^2 + 1$ is a perfect square and its positive square root is known as a Lucas-balancing number [18, 27]. The $n$-th balancing number is denoted by $B_n$ and the balancing numbers satisfy the binary recurrence $B_{n+1} = 6B_n - B_{n-1}$ with initial terms $B_0 = 0, B_1 = 1$. The $n$-th Lucas-balancing number is denoted by $C_n$ and the Lucas-balancing numbers satisfy the same binary recurrence as that of balancing numbers with different initial terms $C_0 = 1, C_1 = 3$.

For any fixed positive integer $A > 2$, the sequence $\{x_n\}$ defined recursively as $x_{n+1} = Ax_n - x_{n-1}$ with initial terms $x_0 = 0, x_1 = 1$ is known as a balancing-like sequence and for each $n$, $Dx_n^2 + 1$, where $D = A^2 - 4$, is a perfect rational square and its positive square root is known as the $n$-th Lucas-balancing-like number. The Lucas-balancing-like sequence also satisfy a recurrence identical with that of balancing-like sequence, but with different initial values [19, 29]. We call the sequence $\{y_n\}$ defined by $y_n = \sqrt{(A^2 - 4)x_n^2 + 4}$,
an associated balancing-like sequence. It is easy to see that the sequence \( \{y_n\} \) satisfies a binary recurrence identical with the balancing-like sequence but with initial terms \( y_0 = 2, y_1 = A \). The Binet forms of the balancing-like and the associated balancing-like sequences are

\[
(1.1) \quad x_n = \frac{\alpha^n - \beta^n}{\alpha - \beta}, \quad y_n = \alpha^n + \beta^n
\]

respectively, where \( \alpha = \frac{A + \sqrt{A^2 - 4}}{2} \) and \( \beta = \frac{A - \sqrt{A^2 - 4}}{2} \). The Pell-like sequence \( \{p_n\} \) and the associated Pell-like sequence \( \{q_n\} \) corresponding to a balancing-like sequence \( \{x_n\} \) are defined by

\[
p_{2n} = 2x_n, \quad p_{2n+1} = x_{n+1} - x_n, \quad q_{2n} = \frac{x_{n+1} - x_n}{2}, \quad q_{2n+1} = x_{n+1} + x_n \quad [20].
\]

We call the sequence \( s_n = \{2q_n\} \), the Lucas-Pell-like sequence.

If \( A \) and \( B \) are fixed nonzero coprime integers, then the sequence \( \{u_n\}_{n \geq 0} \) defined recursively by \( u_{n+1} = Au_n + Bu_{n-1} \), with initial terms \( u_0 = 0, u_1 = 1 \) is known as a Lucas sequence. The corresponding associated Lucas sequence \( \{v_n\}_{n \geq 0} \) satisfies an identical recurrence relation with initial terms \( v_0 = 2 \) and \( v_1 = A \). The Binet forms of these sequences are

\[
u_n = \frac{\gamma^n - \delta^n}{\gamma - \delta}, \quad v_n = \gamma^n + \delta^n
\]

respectively, where \( \gamma = \frac{A + \sqrt{A^2 + 4B^2}}{2} \) and \( \delta = \frac{A - \sqrt{A^2 + 4B^2}}{2} \). If \( B = -1 \), then the sequences \( \{u_n\} \) and \( \{v_n\} \) coincide with the balancing-like sequence \( \{x_n\} \) and the associated balancing-like sequence \( \{y_n\} \) respectively.

The well-known Brocard-Ramanujan problem consists of finding all positive integer solutions of the Diophantine equation

\[
(1.2) \quad n! + 1 = m^2.
\]

This problem was posed by Brocard [5, 6] and independently by Ramanujan [25, 26], unknowing of Brocard’s query. The only known solutions of this problem are \( (n, m) = (4, 5), (5, 11), (7, 71) \) and it is still an open question whether there exists any other solution of (1.2). Overholt [17] showed that the fulfilment of weaker version of the abc-conjecture implies the finiteness of number of solutions of (1.2). Berndt and Galway [3] did not find further solutions of (1.2) for \( 8 \leq n \leq 10^9 \) and recently, Matson and Robert [15] improved the upper bound to \( 10^{12} \).

For \( A \in \mathbb{Z} \), Dabrowski [8] generalized the Brocard-Ramanujan problem and proved the finiteness of the integer solutions of \( n! + A = m^2 \). Berend and Harmse [2] studied the generalized version \( n! = P(x) \) of (1.2), where \( P(x) \) is a polynomial, and showed that the later equation has only finitely many solutions if \( P(x) \) has an irreducible factor of relatively large degree.
Dabrowski and Ulas [9] worked on an equation of the form \( y^2 = BU_n + A \), where \( U_n = f(1)f(2) \cdots f(n) \), \( f \) is an increasing function from \( \mathbb{N} \) to \( \mathbb{N} \).

By replacing the consecutive natural numbers 1, 2, \ldots, \( n \) with terms of a Lucas sequence \( \{u_n\} \), Luca and Shorey [13] proved that the Diophantine equation

\[
u_n u_{n+1} \cdots u_{n+k-1} + t = y^2,
\]

where \( t \) is not a perfect power, has finitely many solutions. Subsequently, Marques [14] proved that the Fibonacci version of Brocard-Ramanujan equation

\[
F_n F_{n+1} \cdots F_{n+k-1} + 1 = F_m^2,
\]

has no solution in positive integers \( m, n \) and \( k \geq 2 \). Generalizing the above equation, Szalay [31] studied the Diophantine equation

\[
H_n H_{n+1} \cdots H_{n+k} + 1 = H_m^2
\]

where \( \{H_n\} \) is either Fibonacci sequence or Lucas sequence or balancing sequence. With a slight modification of the above equation, Pongsriiam [23, 24] solved the equations of the form

\[
A_n^1 A_n^2 \cdots A_n^k \pm 1 = A_m^2 \text{ or } G_m^2
\]

and

\[
A_1 A_2 \cdots A_k \pm 1 = A_m \text{ or } G_m,
\]

where \( \{A_n\}_{n \geq 0} \) and \( \{G_m\}_{m \geq 0} \) are either the Fibonacci or the Lucas sequence. As an extension of the works of Marques [14], Szalay [31], Pongsriiam [23] and Pink and Szikszai [21] solved the Brocard-Ramanujan-type equations

\[
u_n u_{n+1} \cdots u_{n+k} + 1 = u_m^2
\]

and

\[
v_n^1 v_n^2 \cdots v_n^k + 1 = v_m^2
\]

except a certain case, where \( \{u_n\}_{n \geq 0} \) and \( \{v_n\}_{n \geq 0} \) are the Lucas and associated Lucas sequences corresponding to \( B = \pm 1 \) respectively.

Motivated by the above works, we study the Brocard-Ramanujan-type equation

\[
A_n^1 A_n^2 \cdots A_n^k \pm 1 = A_m \text{ or } G_m \text{ or } G_m^2,
\]

where \( \{A_n\}_{n \geq 0} \) and \( \{G_m\}_{m \geq 0} \) are either balancing-like or associated balancing-like sequences.

2. Preliminaries

Let \( a \) and \( b \) be complex numbers, \( a + b = \sqrt{R}, \ ab = Q, R \) and \( Q \) are coprime nonzero integers and \( \frac{a}{b} \) is not a root of unity. The Lehmer sequence is defined as

\[
U_n = \begin{cases} 
\frac{a^n - b^n}{a - b} & \text{if } n \text{ is odd}, \\
\frac{a^n - b^n}{a^2 - b^2} & \text{if } n \text{ is even}
\end{cases}
\]
and its associated Lehmer sequence is

\[ V_n = \begin{cases} \frac{a^n + b^n}{a + b} & \text{if } n \text{ is odd,} \\ a^n + b^n & \text{if } n \text{ is even.} \end{cases} \] (2.4)

Lehmer numbers are generalizations of Lucas numbers on the divisibility properties and was studied by Lehmer himself in 1930. One can observe that Lucas numbers are also Lehmer numbers up to possible multiplication by a factor \(a + b\). In particular,

\[ u_n = \begin{cases} U_n & \text{if } n \text{ is odd,} \\ (a + b)U_n & \text{if } n \text{ is even.} \end{cases} \]

Using the positive integer solutions of the quadratic Diophantine equation

\[ ax^2 - by^2 = 1, \] (2.5)

[32], Keskin and Siar [10] proved that if \((u, v)\) is the fundamental solution of (2.5), then all positive integer solutions of the (2.5) are \((x, y) = (u(x_{n+1} - x_n), v(x_{n+1} + x_n))\) where \(\{x_n\}\) is a balancing-like sequence corresponding to \(A = 4a^2 - 2\). Thus, the positive solutions of \((A + 2)x^2 - (A - 2)y^2 = 4\) are given by \((x_{n+1} - x_n, x_{n+1} + x_n), n \geq 0\). Furthermore, it is easy to see that

\[ p_{2n+1} = x_{n+1} - x_n = \frac{w^{2n+1} + z^{2n+1}}{w + z}, \] (2.6)

\[ s_{2n+1} = 2(x_{n+1} + x_n) = 2 \cdot \frac{w^{2n+1} - z^{2n+1}}{w - z}, \] (2.7)

\[ s_{2n} = w^{2n} + z^{2n}, \quad P_{2n} = \frac{u^{2n} - z^{2n}}{w^2 - z^2}, \] (2.8)

where \(w = \frac{\sqrt{A + 2} + \sqrt{A - 2}}{2}\) and \(z = \frac{\sqrt{A + 2} - \sqrt{A - 2}}{2}\). Since \((w + z)^2\) and \(wz\) belong to set of non-zero integers and are coprime, the Lehmer and the associated Lehmer numbers corresponding to \(w\) and \(z\) are

\[ U_{2n} = \frac{p_{2n}}{2}, \quad U_{2n+1} = \frac{s_{2n+1}}{2}, \] (2.9)

\[ V_{2n} = s_{2n}, \quad V_{2n+1} = p_{2n+1}. \] (2.10)

A prime number \(p\) is a primitive prime divisor of the Lucas number \(u_n\) if \(p\) divides \(u_n\), but does not divide \((\gamma - \delta)^2 u_2 \cdots u_{n-1}\). In Lehmer sequence, \(p\) is a primitive prime divisor of \(U_n\) if \(p\) \(\mid U_n\) and \(p \nmid (a^2 - b^2)^2 U_2 \cdots U_{n-1}\). Since \(u_{2n} = u_n v_n\) by Lemma 2.3(1), it follows that a primitive prime divisor of \(u_{2n}\) is also a primitive prime divisor of \(v_n\).
The following two lemmas deal with the existence conditions for the primitive prime divisors in the Lucas and the Lehmer sequences. These lemmas will be required in the main results of this paper.

**Lemma 2.1.** ([7]) Suppose γ and δ are real numbers such that γ + δ and γδ are nonzero coprime integers and γδ⁻¹ is not a root of unity. If n ≠ 1, 2, 6, then uₙ has a primitive prime divisor except when n = 12, γ + δ = 1 and γδ = −1.

**Lemma 2.2.** ([33]) If a and b are real numbers and n > 18, then Uₙ has a primitive divisor.

To explore the solutions of some Brocard-Ramanuja-type equations, we need to use some properties of Lucas and associated Lucas sequences, which are given in the following lemma.

**Lemma 2.3.** If m and n are natural numbers, then
1. \( u_{2n} = u_nv_n, U_{2n} = U_nV_n, \)
2. \( v_n^2 - (A^2 - 4B)u_n^2 = 4(\alpha\beta)^n, \)
3. \( u_m|u_n \) if and only if \( m|n, \)
4. \( v_m|v_n \) if and only if \( m|n \) and \( \frac{n}{m} \) is odd,
5. if \( m = 2^cm' \) and \( n = 2^dn' \), \( m' \) and \( n' \) are odd, then
   \( (u_m, v_n) = \begin{cases} v_{(m,n)} & \text{if } c > d, \\ 1 \text{ or } 2 & \text{if } c \leq d. \end{cases} \)

For the proofs of the assertions (1)-(4), see [28] and for the proof of (5) see [16].

To establish the main results of this paper, we also need certain factorization properties of balancing-like and associated balancing-like numbers. The following lemma is important in this regard.

**Lemma 2.4.** The balancing-like sequence \( \{x_n\}_{n \geq 0} \) and associated balancing-like sequence \( \{y_n\}_{n \geq 0} \) corresponding to any \( A > 2 \) satisfy
1. \( x_n^2 - 1 = x_{n-1}x_{n+1}, y_n^2 - 1 = \frac{x_ny_n}{x_n}, \)
2. \( x_n + 1 = \begin{cases} \frac{x_n + 1}{2}y_{n-1} & \text{if } n \text{ is odd}, \\ \frac{x_n + 1}{2}p_{n-1}s_{n+1} & \text{if } n \text{ is even}, \end{cases} \)
3. \( x_n - 1 = \begin{cases} \frac{x_n - 1}{2}y_{n+1} & \text{if } n \text{ is odd}, \\ \frac{x_n - 1}{2}p_{n+1}s_{n-1} & \text{if } n \text{ is even}, \end{cases} \)
4. \( y_n + 1 = \begin{cases} \frac{x_n}{2} & \text{if } n \text{ is even}, \\ \frac{x_n}{2}s_n & \text{if } n \text{ is odd}, \end{cases} \)
5. \( y_n - 1 = \begin{cases} \frac{y_n}{2} & \text{if } n \text{ is even}, \\ \frac{y_n}{2}s_n & \text{if } n \text{ is odd}. \end{cases} \)
The above assertions can be proved using (1.1), (2.4), (2.5) and (2.8).

The following Lemma, which is also important for the development of main results, provides conditions under which balancing-like numbers are expressible as products of associated balancing-like numbers.

**Lemma 2.5.** For \( m \geq 5 \), the \( m \)-th balancing-like number \( x_m \) corresponding to some \( A > 2 \) can be written as

\[
x_m = y_{n_1}y_{n_2} \cdots y_{n_k},
\]

where \( y_{n_i} \) is \( n_i \)-th associated balancing-like number, \( 0 \leq n_1 \leq n_2 \leq \cdots \leq n_k \), only if \( m = 2^l, l \geq 3 \) or \( m = 3 \cdot 2^l, l \geq 1 \).

**Proof.** If \( m \geq 5 \) is odd, then in view of Lemma 2.1, there exists an odd primitive prime divisor \( p \) of \( x_m \). By virtue of Lemma 2.3(5), \( p \) does not divide any associated balancing-like number and therefore, \( x_m \) cannot be expressed as a product of associated balancing-like numbers.

Now let \( m \geq 5 \) be even. Then we can write \( m = m_1 \cdot 2^l \), \( l \geq 1 \), \( m_1 \geq 1 \) is odd. If \( m_1 \geq 5 \), then by Lemmas 2.1 and 2.3(5), there exists a prime \( p \) such that \( p|\ x_{m_1} \), but \( p \) does not divide any associated balancing-like number. Since \( m_1|m \), by Lemma 2.3(3) \( p|x_m \) and this implies that \( p|y_{n_i} \) for some \( 1 \leq i \leq k \), which contradicts the fact that \( p \) does not divide any associated balancing-like number. Hence, for \( m_1 \geq 5 \), \( x_m \) is not expressible as product of associated balancing-like numbers. Thus, \( m_1 = 1 \) or 3 and consequently \( m = 2^l, l \geq 3 \) or \( m = 3 \cdot 2^l, l \geq 1 \).

If \( m = 2^l \) and \( l \geq 3 \), then

\[
x_{2^l} = y_{2^{l-1}}y_{2^{l-2}} \cdots y_2 y_1,
\]

and in this case, \( x_{2^l} \) is product of associated balancing-like numbers. Furthermore, if \( m = 3 \cdot 2^l \) and \( l \geq 1 \), then

\[
x_{3 \cdot 2^l} = y_{3 \cdot 2^{l-1}}y_{3 \cdot 2^{l-2}} \cdots y_6 y_3 y_1.
\]

Since \((x_3, y_n) = 1 \) or 2 for all \( n \) by Lemma 2.3(5), \( x_3 \) is expressible as product of associated balancing-like numbers only if \( x_3 = A^2 - 1 = 2^r \) for some \( r \geq 3 \) since \( A > 2 \). Hence, (2.11) holds only when \( m = 2^l, l \geq 3 \) or \( m = 3 \cdot 2^l, l \geq 1 \).

\( \square \)

3. Main Results

In this section, we study some Brocard-Ramanujan-type equations that involve balancing-like and associated balancing-like numbers. These results are variants of the works done in [14], [31], [23, 24], [21] for other sequences. In the proof of our main results, we use factorizations of balancing-like and associated balancing-like numbers, some results from [7, 33] on the existence of primitive prime divisors of Lucas and Lehmer numbers and Lemma 2.5.
Throughout this section, \( \{x_n\}_{n \geq 0} \) and \( \{y_n\}_{n \geq 0} \) denote the balancing-like and associated balancing-like sequences respectively, \( m, n_1, n_2, \ldots, n_k \) are nonnegative integers such that \( n_1 \leq n_2 \leq \cdots \leq n_k \) and \( k \) is a natural number.

**Theorem 3.1.** If \( A \neq 3 \), then the equation
\[
x_{n_1} x_{n_2} \cdots x_{n_k} + 1 = y_m^2
\]
holds only if \( k = 1, n_1 = 3 \) and \( m = 1 \). Moreover, if \( A = 3 \), then (3.13) holds only if \( k = 1, n_1 = 3, m = 1 \) or \( k = 1, n_1 = 2, m = 0 \).

**Proof.** Using Lemma 2.4, (3.13) can be written as
\[
x_{n_1} \cdots x_{n_k} x_m = x_{3m}.
\]
If \( m > 2 \), then by Lemma 2.1, \( x_{3m} \) has a primitive prime divisor \( p \) that does not divide \( x_k \) for \( k < 3m \) and hence, if \( n_k < 3m \), then \( p \) does not divide any term on the left hand side of (3.14). If \( n_k > 3m \), then there exists a primitive prime divisor of \( x_{n_k} \) that does not divide \( x_{3m} \). Therefore, \( 3m = n_k \) and hence (3.14) reduces to
\[
x_{n_1} \cdots x_{n_k-1} x_m = 1,
\]
which is not possible since \( m > 2 \). If \( m = 1, y_m^2 - 1 = A^2 - 1 = x_3 \) and for \( m = 0, y_m^2 - 1 = 2^2 - 1 = 3 \), which holds only if \( A = 3 \). If \( m = 2 \), then (3.13) reduces to
\[
x_{n_1} x_{n_2} \cdots x_{n_k} = y_2^2 - 1 = A^4 - 4A^2 + 3.
\]
One can check that \( A^4 - 4A^2 + 3 < x_5 \) and hence, \( n_k \) cannot exceed 4. But the only \( x_i, 2 \leq i \leq 4 \) that divides \( A^4 - 4A^2 + 3 \) is \( x_3 = A^2 - 1 \) and \( A^4 - 4A^2 + 3 = x_3(A^2 - 3) \). Furthermore, \( (A^2 - 3) < x_3 \) and is divisible by \( x_2 = A \) only if \( A = 3 \) and in this case \( A^4 - 4A^2 + 3 = 2x_3x_2 \) and 2 is not a balancing-like number. Hence (3.15) cannot hold for any \( k \).

**Theorem 3.2.** The Diophantine equation
\[
y_{n_1} \cdots y_{n_k} + 1 = x_m^2
\]
has no solution for \( m > 5 \). If \( m \leq 5 \), then for each \( A > 2 \), (3.16) has at most a finite number of solutions.

**Proof.** If \( m = 3 \), then \( x_3^2 - 1 = x_2x_4 = y_3^2y_2 \), which is a solution of (3.16) corresponding to \( k = 3, n_1 = n_2 = 1, n_3 = 2 \). If \( m \leq 5 \), then it is easy to see that for each \( A > 2 \), (3.16) has at most \( 5^2 - 1 = 155 \) solutions. Now assume that \( m > 5 \). Using Lemma 2.4, (3.16) can be written as
\[
y_{n_1} \cdots y_{n_k} = x_{m+1}x_{m-1}.
\]
Since \( y_n = \frac{x_{n+1}x_n}{x_n} \), applying Lemma 2.3 to (3.17), we get
\[
x_{2n_1} \cdots x_{2n_k} = x_{m+1}x_{m-1}x_{n_1} \cdots x_{n_k}.
\]
If \( m + 1 > 2n_k \), then by Lemma 2.1, no primitive prime divisor of \( x_{m+1} \) divides any term on the left hand side of (3.18). If \( m + 1 < 2n_k \), then no primitive prime divisor of \( x_{2n_k} \) divides any term on the right hand side of (3.18). Hence, \( 2n_k = m + 1 \) which reduces (3.18) to

\[
x_{2n_1} \cdots x_{2n_{k-1}} = x_{m-1}x_{n_1} \cdots x_{n_k}.
\]

Since \( n_k = \frac{m+1}{2} < m - 1 \), using the above argument repeatedly, one can conclude that \( m - 1 = 2n_{k-1}, n_k = 2n_{k-2} \) and \( n_{k-1} = 2n_{k-3} \), which imply that \( m + 1 = 2n_k = 4n_{k-2} \) and \( m - 1 = 2n_{k-1} = 4n_{k-3} \). Therefore, \( 4|m - 1 \) and \( 4|m + 1 \), which leads to \( 4|(m + 1) - (m - 1) = 2 \), which is a contradiction. Hence, (3.16) has no solution for \( m > 5 \).

Theorem 3.3. The Diophantine equation

\[
(x_0 x_1 x_2 \cdots x_{n-1} - 1 = x_m)
\]

has no solution for \( m > 19 \). If \( 0 \leq m \leq 19 \), then for each \( A > 2 \), (3.19) can have at most finitely many solutions.

Proof. If \( m = 0 \), then \( x_0 + 1 = x_1 \) and if \( m = 3 \), then \( x_3 + 1 = A^2 = x_2^2 \) leading to the solutions of (3.19). For \( 0 \leq m \leq 19 \), using simple combinatorial argument, it is easy to see that (3.19) cannot have more than \( 20(2^{18} - 1) \) possible solutions. Now, let \( m > 19 \). If \( m \) is odd, then by virtue of Lemma 2.4, (3.19) can be written as

\[
x_{n_1} x_{n_2} \cdots x_{n_k} x_{m-1} = x_{m+1} x_{m-1}.
\]

By Lemma 2.3(1) makes (3.20) equivalent to

\[
x_{n_1} x_{n_2} \cdots x_{n_k} x_{m-1} = x_{m+1} x_{m-1}.
\]

If \( m - 1 < n_k \), then there exists a prime divisor \( p \) such that \( p|x_{n_k} \), but \( p \) does not divide \( x_{m+1} \) and \( x_{m-1} \). If \( m - 1 > n_k \), there exists a prime \( p \) that divides \( x_{m-1} \), but does not divide any \( x_{n_i} \) for \( 1 \leq i \leq k \). Hence, \( m - 1 = n_k \) which reduces (3.21) to

\[
x_{n_1} x_{n_2} \cdots x_{n_{k-1}} x_{m-1} = x_{m+1} x_{m-1}.
\]

Since \( \frac{m+1}{2} > \frac{m-1}{2} \), using the similar argument as above we conclude that \( \frac{m+1}{2} = n_{k-1} \) and therefore, (3.22) takes the form

\[x_{n_1} x_{n_2} \cdots x_{n_{k-2}} x_{m-1} = 1.
\]

Using the above equation, we get

\[1 = x_{n_1} x_{n_2} \cdots x_{n_{k-2}} x_{m-1} \geq x_{m-1} > A,
\]
which contradict our assumption \( A > 2 \). If \( m \) is even, then using Lemma 2.4, (3.19) can be written as
\[
x_{n_1} x_{n_2} \cdots x_{n_k} = x_m - 1 = \frac{1}{2} p_{m+1} s_{m-1}.
\]
In view of (2.3) and (2.4), the above equation can be written in terms of Lehmer and associated Lehmer numbers as
\[
U_{2n_1} U_{2n_2} \cdots U_{2n_k} = V_{m+1} U_{m-1},
\]
and in view of Lemma 2.3(1), the last equation is equivalent to
\[
U_{2n_1} U_{2n_2} \cdots U_{2n_k} U_{m+1} = U_{2m+2} U_{m-1}.
\]
Since, by Lemma 2.2, the Lehmer number \( U_n \) has a primitive prime divisor for \( n > 18 \), it follows that \( 2m+2 = 2n_k \), and using Lemma 2.2 once more, we get \( m - 1 = 2n_{k-1} \). Now, we conclude from (3.23) that
\[
1 = U_{2n_1} U_{2n_2} \cdots U_{2n_{k-2}} U_{m+1} \geq U_{m+1} > U_3,
\]
which is not possible and hence, (3.19) has no solution for \( m > 19 \).

**Theorem 3.4.** The Diophantine equation
\[
x_{n_1} x_{n_2} \cdots x_{n_k} + 1 = x_m
\]
has no solution for \( m > 17 \) and (3.24) may be solvable for \( m \leq 17 \) depending on the values of \( A \).

**Proof.** If \( m = 1 \), then \( x_1 - 1 = x_0 \), which is a solution of (3.24). If \( m \leq 17 \), it is easy to check the possible solutions of (3.24) for different values of \( A \). Now assume that \( m > 17 \). If \( m \) is odd, then using Lemma 2.4 to (3.24), we get
\[
x_{n_1} x_{n_2} \cdots x_{n_k} = \frac{x_{m-1} y_{m+1}}{2}.
\]
Using Lemma 2.3(1), the above equation can be written as
\[
x_{n_1} x_{n_2} \cdots x_{n_{k-1}} x_{m+1} = x_{m-1} x_{m+1}.
\]
In view of Theorem 2.1, \( m + 1 = n_k \) and hence (3.25) reduces to
\[
x_{n_1} x_{n_2} \cdots x_{n_{k-1}} x_{m+1} = x_{m-1},
\]
which is not possible since the left hand side is greater than right hand side.

If \( m \) is even, then application of Lemma 2.4, (3.24) results in
\[
x_{n_1} x_{n_2} \cdots x_{n_k} = \frac{1}{2} p_{m-1} s_{m+1}.
\]
Using (2.3) and (2.4), the above equation can be written in terms of Lehmer and associated Lehmer numbers as
\[
U_{2n_1} U_{2n_2} \cdots U_{2n_k} = V_{m-1} U_{m+1}.
\]
An application of Lemma 2.3(1) makes the last equation equivalent to
\[(3.26) \quad U_{2n_1} U_{2n_2} \cdots U_{2n_k} U_{m-1} = U_{2m-2} U_{m+1}.\]
Applying Lemma 2.2 to (3.26), we get \(2m - 2 = 2n_k\). Using Lemma 2.2 once more, we get \(m + 1 = 2n_{k-1}\), and this reduces (3.26) to
\[(3.27) \quad U_{2n_1} U_{2n_2} \cdots U_{2n_{k-2}} U_{m-1} = 1,\]
which is not possible since \(U_{m-1} > 1\) for \(m > 17\). Hence, (3.24) has no solution for \(m > 17\).

**Theorem 3.5.** The Diophantine equation
\[(3.28) \quad y_{n_1} y_{n_2} \cdots y_{n_k} - 1 = y_m\]
has no solution for \(m > 12\).

**Proof.** If \(m > 12\) is even, then using Lemma 2.4, (3.28) can be written as
\[(3.29) \quad y_{n_1} y_{n_2} \cdots y_{n_k} x_m = x_{\frac{m}{2}}.\]
In view of Lemma 2.3(1), (3.29) is equivalent to
\[(3.30) \quad x_{2n_1} x_{2n_2} \cdots x_{2n_k} x_{\frac{m}{2}} = x_{2m} x_{n_1} x_{n_2} \cdots x_{n_k}.\]
An application of Lemma 2.1 to (3.30) results in
\[(3.31) \quad x_{2n_1} x_{2n_2} \cdots x_{2n_k} x_{\frac{m}{2}} = x_{n_1} x_{n_2} \cdots x_{n_k}.\]
Since \(7 \leq \frac{m}{2} = \frac{2n_k}{3} < n_k\), similar to the last case, one can use Lemma 2.1 to obtain \(n_k = 2n_{k-1}\) and hence, \(n_{k-1} = \frac{m}{2}\) and (3.31) further reduces to
\[y_{n_1} y_{n_2} \cdots y_{n_{k-2}} x_{\frac{m}{2}} = x_{n_{k-1}}.\]
But, \(n_{k-1} = \frac{3m}{8} < \frac{m}{2}\) implies that \(y_{n_1} y_{n_2} \cdots y_{n_{k-2}} x_{\frac{m}{2}} < x_{\frac{m}{2}}\) which is absurd.

If \(m > 12\) is odd, then using Lemma 2.4, (3.28) can be written as
\[y_{n_1} y_{n_2} \cdots y_{n_k} = \frac{p_{3m}}{p_m}.\]
Since \(y_n = s_{2n}\), the above equation leads to
\[s_{2n_1} s_{2n_2} \cdots s_{2n_k} p_m = p_{3m},\]
which, in terms of Lehmer and associated Lehmer numbers, can be written as
\[(3.32) \quad V_{2n_1} V_{2n_2} \cdots V_{2n_k} V_m = V_{3m}.\]
An application of Lemma 2.2 to (3.32) gives \(3m = 2n_k\) and reduces (3.32) to
\[V_{2n_1} V_{2n_2} \cdots V_{2n_{k-1}} V_m = 1,\]
which implies that \(1 \geq V_m > V_{12}\) as \(m > 12\). But, this is not possible. Hence, (3.28) has no solution for \(m > 12\).
Theorem 3.6. The Diophantine equation

\[ y_{n_1}y_{n_2} \cdots y_{n_k} + 1 = y_m \]  

has no solution for \( m > 18 \).

Proof. If \( m > 18 \) is even, then using Lemma 2.4, (3.33) can be written as

\[ y_{n_1}y_{n_2} \cdots y_{n_k} y_{m} = y_{\frac{3m}{2}}. \]

By the help of Lemma 2.1, (3.34) gives \( \frac{3m}{2} = n_k \) and thus, (3.34) reduces to

\[ y_{n_1}y_{n_2} \cdots y_{n_{k-1}} y_{m} = 1, \]

which gives \( 1 \geq y_{\frac{3m}{2}} > y_0 \). But, this is not possible.

If \( m > 18 \) is odd, then using Lemma 2.4 in (3.33), we get

\[ y_{n_1}y_{n_2} \cdots y_{n_k} = \frac{s_{3m}}{s_m}. \]

Since \( y_n = s_{2n} \), (3.35) is equivalent to

\[ s_{2n_1}s_{2n_2} \cdots s_{2n_k} s_m = s_{3m} \]

and converting in terms of Lehmer and associated Lehmer numbers, the last equation is equivalent to

\[ V_{2n_1}V_{2n_2} \cdots V_{2n_k} U_m = U_{3m}. \]

Applying Lemma 2.3(1) in (3.36), we get

\[ V_{2n_1}V_{2n_2} \cdots V_{2n_{k-1}} U_{4n_k} U_{4n_k} U_m = U_{3m} U_{2n_k} U_{2n_k-1}. \]

An application of Lemma 2.2 in (3.37) gives \( 3m = 4n_k \) and hence, \( 2n_k = \frac{3m}{2} > m > 18 \). Using Lemma 2.2 in (3.37) once more, we get \( 2n_k = 4n_{k-1} \) and (3.37) reduces to

\[ V_{2n_1}V_{2n_2} \cdots V_{2n_{k-2}} U_m = U_{2n_k-1}. \]

Since \( 2n_{k-1} = n_k = \frac{3m}{4} < m \), the left hand side of (3.38) is greater than right hand side, which contradicts (3.38). Hence, no solution of (3.33) exists for \( m > 18 \).

Theorem 3.7. The Diophantine equation

\[ x_{n_1}x_{n_2} \cdots x_{n_k} + 1 = y_m \]

has no solution for \( m > 6 \) and it can have at most finite number of solutions for \( m \leq 6 \) for each \( A \).
If \( m = 0 \), then \( x_1 + 1 = y_0 \), which is a solution of (3.39) corresponding to \( k = 1 \) and \( n_1 = 1 \). One can check that (3.39) has at most \( 6(2^5 - 1) = 186 \) solutions if \( m \leq 6 \) for each \( A \). Now assume that \( m > 6 \). If \( m \) is even, then using Lemma 2.4, (3.39) can be written as

\[
x_{n_1} x_{n_2} \cdots x_{n_k} y_{\frac{m}{2}} = y_{\frac{2m}{2}}.
\]

(3.40)

Lemma 2.3(1) makes (3.40) equivalent to

\[
x_{n_1} x_{n_2} \cdots x_{n_k} x_m x_{\frac{2m}{2}} = x_{3m} x_{\frac{2m}{2}}.
\]

(3.41)

Lemma 2.1 applied to (3.41) gives \( 3 \frac{m}{2} = n_k \) and this reduces (3.41) to

\[
x_{n_1} x_{n_2} \cdots x_{n_{k-1}} x_m x_{\frac{2m}{2}} = x_{\frac{2m}{2}},
\]

(3.42)

which is not possible since the left hand side is greater than the right side.

If \( m \) is odd, then with the help of Lemma 2.4, (3.39) can be written as

\[
x_{n_1} x_{n_2} \cdots x_{n_k} = p_3 \frac{m}{2},
\]

which, in terms of Lehmer and associated Lehmer numbers, is equivalent to

\[
U_{n_1} U_{n_2} \cdots U_{n_k} U_m = U_{3m}.
\]

Using Lemma 2.2 in (3.43), we obtain \( n_k = 3m \) and (3.43) reduces to

\[
U_{n_1} U_{n_2} \cdots U_{n_{k-1}} U_m = 1,
\]

which is not true since \( U_m > 1 \) because of our assumption \( m > 6 \). Hence, (3.39) has no solution for \( m > 6 \).

Theorem 3.8. The Diophantine equation

\[
x_{n_1} x_{n_2} \cdots x_{n_k} - 1 = y_m
\]

has no solution for \( m > 4 \) and for each \( A \), it has at most finite number of solutions if \( m \leq 4 \).

Proof. If \( m = 2 \), then \( x_3 - 1 = y_2 \) leading to a solution of (3.44) corresponding to \( k = 1, n_1 = 3 \) and for \( m \leq 4 \), it is easy to see the finiteness of solutions for each \( A \). Now assume that \( m > 4 \). If \( m \) is even, then using Lemma 2.4, (3.44) can be written as

\[
x_{n_1} x_{n_2} \cdots x_{n_k} x_m x_{\frac{2m}{2}} = x_{\frac{2m}{2}}.
\]

(3.45)

Now applying Lemma 2.1 to (3.45), we get that \( \frac{3m}{2} = n_k \) and this reduces (3.45) to

\[
x_{n_1} x_{n_2} \cdots x_{n_{k-1}} x_m x_{\frac{2m}{2}} = 1,
\]

which is not possible since \( x_{\frac{2m}{2}} > 1 \) for \( m > 4 \).

If \( m \) is odd, then using Lemma 2.4, we can write (3.44) as

\[
x_{n_1} x_{n_2} \cdots x_{n_k} = \frac{p_3 m}{p_m},
\]
and this equation can be written in terms of Lehmer and associated Lehmer numbers as

\[ U_{n_1} U_{n_2} \cdots U_{n_k} V_m = V_{3m}. \]

Since \( V_n = U_{2n}/U_n \) from Lemma 2.3(1), the above equation takes the form

(3.46) \[ U_{n_1} U_{n_2} \cdots U_{n_k} U_{2m} U_{3m} = U_m U_{6m}. \]

Using Lemma 2.2 in (3.46), we get \( n_k = 6 \) and (3.46) reduces to

\[ U_{n_1} U_{n_2} \cdots U_{n_{k-1}} U_{2m} U_{3m} = U_m, \]

which does not hold since the left hand side is greater than the right hand side. Hence, (3.44) has no solution for \( m > 4 \).

**Theorem 3.9.** If \( m > 18 \), then the Diophantine equation

(3.47) \[ y_{n_1} y_{n_2} \cdots y_{n_k} - 1 = x_m \]

is solvable only if \( m = 2^{l+1} - 1, l \geq 4 \) or \( 3 \cdot 2^{l+1} - 1, l \geq 2 \). If \( m < 18 \), then for each \( A \), (3.47) has only finite number of solutions.

**Proof.** For \( m = 1 \), \( y_0 - 1 = x_1 \), which is a solution of (3.47) corresponding to \( k = 1 \), \( n_1 = 0 \) and it is easy to check the finiteness of solutions of (3.47) when \( m < 18 \). Now assume that \( m > 18 \). If \( m \) is odd, then using Lemma 2.4, (3.47) can be written as

\[ y_{n_1} y_{n_2} \cdots y_{n_k} = x_m + 1 \]

and with the help of Lemma 2.3, the above equation takes the form

(3.48) \[ y_{n_1} y_{n_2} \cdots y_{n_k - 1} x_{2n_k} x_{m-1} = x_{m+1} x_{n_k} x_{m-1}. \]

Applying Lemma 2.1 to (3.48), we get \( n_k = \frac{m-1}{2} \) and (3.48) reduces to

(3.49) \[ y_{n_1} y_{n_2} \cdots y_{n_k - 2} y_{n_{k-1}} = x_{m+1}. \]

But, in view of Lemma 2.5, (3.49) holds only if \( m = 2^{l+1} - 1, l \geq 4 \) or \( 3 \cdot 2^{l+1} - 1, l \geq 2 \).

If \( m \) is even, then using Lemma 2.4, (3.47) can be written as

\[ y_{n_1} y_{n_2} \cdots y_{n_k} = \frac{1}{2} p_{m-1} s_{n+1}. \]

An use of Lemma 2.3, transforms the above equation to

(3.50) \[ x_{2n_1} x_{2n_2} \cdots x_{2n_k} = p_{m-1} s_{m+1} x_{n_1} x_{n_2} \cdots x_{n_k} \]

and (3.50) can be written in terms of Lehmer and associated Lehmer numbers as

(3.51) \[ U_{4n_1} U_{4n_2} \cdots U_{4n_k} = V_{m-1} U_{m+1} U_{2n_1} U_{2n_2} \cdots U_{2n_k}. \]

With the help of Lemma 2.3, (3.51) takes the form

(3.52) \[ U_{4n_1} U_{4n_2} \cdots U_{4n_k} U_{m-1} = U_{2m-2} U_{m+1} U_{2n_1} U_{2n_2} \cdots U_{2n_k}. \]
By the use of Lemma 2.2 to (3.52) gives $2m - 2 = 4n_k$ and reduces (3.52) to
\[ U_{4n_1}U_{4n_2} \cdots U_{4n_{k-1}} = U_{m+1}U_{2n_1}U_{2n_2} \cdots U_{2n_{k-1}} \]
and Lemma 2.3 reduces the above equation to
\[ (3.53) \quad V_{2n_1}V_{2n_2} \cdots V_{2n_{k-1}} = U_{m+1}. \]
Since $m+1$ is odd, using Lemma 2.2 for $m > 17$, we can ascertain the existence
of a primitive prime divisor of $U_{m+1}$ that does not divide any associated
Lehmer number corresponding to that Lehmer sequence $\{U_n\}$, a contradiction
to (3.53).

**Theorem 3.10.** If $m > 8$, then the Diophantine equation
\[ (3.54) \quad y_{n_1}y_{n_2} \cdots y_{n_k} + 1 = x_m \]
is solvable if $m = 2^l + 1$, $l \geq 3$ or $3 \cdot 2^l + 1$, $l \geq 2$. If $m \leq 8$, then for each $A$,
(3.54) has at most finitely many solutions.

**Proof.** If $m = 3$, $y_2 + 1 = x_3$, which corresponds to a solution of (3.54)
with $k = 1$, $n_1 = 2$. For each $A$, it is easy to see that (3.54) has only finitely
many solutions when $m \leq 8$. Now let $m > 8$. If $m$ is odd, then using Lemma
2.4, (3.54) can be written as
\[ y_{n_1}y_{n_2} \cdots y_{n_k} = x_{m+1}y_{m+1}. \]
Lemma 2.3 makes the above equation equivalent to
\[ y_{n_1}y_{n_2} \cdots y_{n_{k-1}}x_{2n_k}x_{m+1} = x_{m+1}x_{n_k}x_{m+1}. \]
By virtue of Lemma 2.1, (3.55) holds only if $n_k = \frac{m+1}{2}$ and consequently,
(3.55) reduces to
\[ (3.56) \quad y_{n_1}y_{n_2} \cdots y_{n_{k-1}} = x_{m+1}. \]
Using Lemma 2.5, one can see that (3.56) hold if $m = 2^l + 1$, $l \geq 3$ or
$3 \cdot 2^l + 1$, $l \geq 2$.

If $m$ is even, applying Lemma 2.4 to (3.54), we get
\[ y_{n_1}y_{n_2} \cdots y_{n_k} = p_{m+1}s_{m-1} \]
and using Lemma 2.3, the above equation can be written as
\[ (3.57) \quad x_{2n_1}x_{2n_2} \cdots x_{2n_k} = p_{m+1}s_{m-1}x_{n_1}x_{n_2} \cdots x_{n_k}. \]
Writing (3.57) in terms of the Lehmer and the associated Lehmer numbers,
we get
\[ (3.58) \quad U_{4n_1}U_{4n_2} \cdots U_{4n_k} = V_{m+1}U_{m-1}U_{2n_1}U_{2n_2} \cdots U_{2n_k}. \]
The relation $U_{2n} = U_nV_n$ makes it possible to write (3.58) as
\[ (3.59) \quad U_{4n_1}U_{4n_2} \cdots U_{4n_k}U_{m+1} = U_{2m+2}U_{m-1}U_{2n_1}U_{2n_2} \cdots U_{2n_k}. \]
Applying Lemma 2.2 to (3.59), we get $2n_k = m + 1$ and now (3.59) takes the form

$$U_{4n_1}U_{4n_2} \cdots U_{4n_{k-1}} = U_{m-1}U_{2n_1}U_{2n_2} \cdots U_{2n_{k-1}}$$

and using Lemma 2.3, we can reduce the above equation to

$$(3.60) \quad V_{2n_1}V_{2n_2} \cdots V_{2n_{k-1}} = U_{m-1}.$$  

Since $m - 1 > 18$ is odd, Lemma 2.2 guarantees the existence of a primitive prime divisor $p$ of $U_{m-1}$, which does not divide any associated Lehmer number, a contradiction to (3.60).

**Acknowledgment:** It is our pleasure to thank both the anonymous referees for their valuable suggestions and comments which result in the presentation and accuracy of the paper vastly.
