

TORSION OF RATIONAL ELLIPTIC CURVES OVER CUBIC FIELDS AND SPORADIC POINTS ON $X_1(n)$

FILIP NAJMAN

ABSTRACT. We classify the possible torsion structures of rational elliptic curves over cubic fields. Along the way we find a previously unknown torsion structure over a cubic field, $\mathbb{Z}/21\mathbb{Z}$, which corresponds to a sporadic point on $X_1(21)$ of degree 3, which is the lowest possible degree of a sporadic point on a modular curve $X_1(n)$.

1. INTRODUCTION

When trying to understand elliptic curves over number fields, an important problem is to classify the possible torsion structures. The first such classification was done by Mazur [26, 27], proving that the torsion of an elliptic curve over \mathbb{Q} has to be isomorphic to one of the following 15 groups:

$$(1) \quad \begin{aligned} &\mathbb{Z}/m\mathbb{Z}, 1 \leq m \leq 12, m \neq 11, \\ &\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2m\mathbb{Z}, 1 \leq m \leq 4. \end{aligned}$$

After this result, attention shifted toward number fields. Kamienny [16, Theorem 3.1] proved that if a torsion point of an elliptic curve over a quadratic field has prime order p , then $p \leq 13$. This, when combined with a theorem of Kenku and Momose [22, Theorem (0.1).], gave a complete list of possible torsion structures over quadratic fields:

$$(2) \quad \begin{aligned} &\mathbb{Z}/m\mathbb{Z}, 1 \leq m \leq 18, m \neq 17, \\ &\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2m\mathbb{Z}, 1 \leq m \leq 6, \\ &\mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/3m\mathbb{Z}, m = 1, 2, \\ &\mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}. \end{aligned}$$

The author gave a similar complete list for the fields $\mathbb{Q}(i)$ and $\mathbb{Q}(\sqrt{-3})$ (see [33, Theorem 2.]), and a procedure how to make such a list was developed by Kamienny and the author [17].

As one can see, much is known about the possible torsion structures of elliptic curves over \mathbb{Q} and over quadratic fields. Unfortunately, already over cubic fields a classification of possible torsion structures of elliptic curves is not known. However, it is known that if an elliptic curve over a cubic field

has a point of prime order p , then $p \leq 13$ (see [36, 37]). Jeon, Kim and Schweizer [13, Theorem 3.4.] found all the torsion structures that appear infinitely often as one runs through all elliptic curves over all cubic fields:

$$(3) \quad \begin{aligned} &\mathbb{Z}/m\mathbb{Z}, 1 \leq m \leq 20, m \neq 17, 19, \\ &\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2m\mathbb{Z}, 1 \leq m \leq 7. \end{aligned}$$

Jeon, Kim and Lee [11] constructed infinite families having each of the torsion structures from the list (3).

However, it was unknown whether the list (3) is complete, i.e. if one runs through all elliptic curves over all cubic fields, do there exist torsion structures that appear only finitely many times? We show, by finding an elliptic curve with torsion $\mathbb{Z}/21\mathbb{Z}$ over a cubic field, that the answer is yes and that the list (3) is not the complete list of possible torsion structures over cubic fields. Note that this, in contrast with what happens over \mathbb{Q} and over quadratic fields, where each group that can appear at all, is the torsion group of infinitely many non-isomorphic elliptic curves.

The main purpose of this paper is to study the possible torsion structures of all rational elliptic curves (meaning that all their coefficients are \mathbb{Q} -rational) over all cubic fields. This is a natural question to consider as, apart from being interesting in itself, it is often important to study rational elliptic curves over extensions of \mathbb{Q} when solving Diophantine equations (see for example [2]). Somewhat similar problems were studied by Fujita [8], who studied the possible torsion groups of rational elliptic curves over the compositum of all quadratic fields, by Lozano-Robledo [25], who studied the minimal degree of the field of definition of points of order p on rational elliptic curves and by González-Jiménez and Tórn timer [14], who studied how can the torsion of a rational elliptic curve grow upon base changing to a quadratic field.

The main result of this paper is the following theorem.

Theorem 1. *Let E/\mathbb{Q} be a rational elliptic curve, and let K/\mathbb{Q} be a cubic extension. Then $E(K)_{tors}$ is one of the following groups*

$$(4) \quad \begin{aligned} &\mathbb{Z}/m\mathbb{Z}, m = 1, \dots, 10, 12, 13, 14, 18, 21, \\ &\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2m\mathbb{Z}, m = 1, 2, 3, 4, 7. \end{aligned}$$

The elliptic curve 162B1 over $\mathbb{Q}(\zeta_9)^+$ is the unique rational elliptic curve over a cubic field with torsion $\mathbb{Z}/21\mathbb{Z}$. For all the other groups T in the list (4), there exists infinitely many rational elliptic curves that have torsion T over some cubic field.

To prove Theorem 1, we will first need to solve the analogous problem for quadratic fields, which we do in Section 3.

We prove Theorem 1 by studying the action of the Galois group on the torsion points, division polynomials, and by finding the rational points on certain (modular) curves.

Let us mention that a somewhat similar problem to the one considered in this paper is the problem of finding the possible torsion structures of rational elliptic curves with integral j -invariant [32, 38] and with complex multiplication over number fields [5, 3].

Recall that the *gonality* $\gamma(X)$ of an algebraic curve X is the lowest degree of a nonconstant rational map from X to the projective line. We call points of degree d on the modular curves $Y_1(m, n)$ (see Section 2 for definitions of modular curves and note that we only consider modular curves with $m = 1, 2$ in this paper), when $d < \gamma(Y_1(m, n))$ *sporadic*. Since all the modular curves $Y_1(m, n)$ that correspond to the torsion structures in the list(1) are of genus 0 and have (infinitely many) rational points (since some of the cusps of $X_1(m, n)$ are rational) and hence are of gonality 1. Similarly, all the modular curves $Y_1(m, n)$ that correspond to the torsion structures in the list (2) are of genus ≤ 2 (and hence have gonality 1 or 2), so it follows that there are no sporadic points of degree 1 or 2. Van Hoeij [40] found sporadic points of degree 6 on $X_1(37)$ (of gonality 18), and of degree 9 on $X_1(29)$ and $X_1(31)$ (of gonality 11 and 12, respectively).

Since the modular curve $X_1(21)$ has gonality 4, the unique rational elliptic curve with 21-torsion over a cubic field gives us a degree 3 sporadic point, which is the lowest degree possible. By the method used to construct this point we rediscover van Hoeij's degree 6 point on $X_1(37)$.

2. CONVENTIONS AND NOTATION

Throughout this paper, K will be a cubic field and L will be its normal closure over \mathbb{Q} . This means that when K/\mathbb{Q} is normal, then $L = K$, and otherwise L is a degree 6 extension of \mathbb{Q} such that $\text{Gal}(L/\mathbb{Q}) \simeq S_3$. We denote by M the unique field with the property that M is a subfield of L such that $[L : M] = 3$ (from which it follows that $\text{Gal}(L/M) \simeq \mathbb{Z}/3\mathbb{Z}$). If K is normal over \mathbb{Q} , this will mean that $M = \mathbb{Q}$.

Let $E[n] = \{P \in E(\overline{\mathbb{Q}}) | nP = 0\}$ denote the n -th division group of E over $\overline{\mathbb{Q}}$ and let $\mathbb{Q}(E[n])$ be the n -th division field of E .

We will denote by E^d a quadratic twist of E by $d \in \mathbb{Q}^*/(\mathbb{Q}^*)^2$. By ζ_n we will denote a n th primitive root of unity and by $\mathbb{Q}(\zeta_n)^+$ the maximal real subfield of $\mathbb{Q}(\zeta_n)$.

For n an odd positive integer, we denote by ψ_n the n -th division polynomial of an elliptic curve E (see [41, Section 3.2] for details), which satisfies that, for a point $P \in E$, $\psi_n(x(P)) = 0$ if and only if $nP = 0$. As before, although the division polynomial depends on the curve E , we will leave E out of the index as it will be clear what elliptic curve we are referring to.

Let E/\mathbb{Q} be an elliptic curve and $d > 1$ be an integer. Factor ψ_n and then consider all factors of degree l , where $l|d$. Each of these factors generates a field F over which the x -coordinate of a point P such that $nP = 0$ is defined. The torsion point P is then defined over F' which is either F itself or a quadratic extension of F obtained by adjoining the y -coordinate of P .

By considering all such fields F' of degree dividing d , we can check whether a fixed rational elliptic curve E obtains n -torsion over some extension of degree d . We call this method the *division polynomial method*.

The division polynomial method can also be effectively used in determining which, if any, twists of a given curve E/F have non-trivial n -torsion over the base field. This is done by finding all the quadratic extensions $F(\sqrt{d})$ in which the n -torsion grows and then computing for which of the finitely many d obtained does the curve $E^d(F)$ have non-trivial n -torsion.

If there exists a K -rational cyclic isogeny $\phi : E \rightarrow E'$ of degree n , this implies that $\ker \phi$ is $\text{Gal}(\bar{K}/K)$ -invariant cyclic group of order n and we will say that E/K has an n -isogeny.

When counting rational elliptic curves, unless stated otherwise, we will count up to \mathbb{Q} -isomorphism. When referring to specific elliptic curves we will list them as they appear in Cremona's tables [4], as we already did in Theorem 1.

Let $m|n$ and denote by $Y_1(m, n)$ the affine modular curve whose K -rational points classify isomorphism classes of the triples (E, P_m, P_n) , where E is an elliptic curve (over K) and P_m and P_n are torsion points (over K) which generate a subgroup isomorphic to $\mathbb{Z}/m\mathbb{Z} \oplus \mathbb{Z}/n\mathbb{Z}$. For simplicity, we write $Y_1(n)$ instead of $Y_1(1, n)$. Let $X_1(m, n)$ be the compactification of the curve $Y_1(m, n)$ obtained by adjoining its cusps.

Denote by $Y_0(n)$ the affine curve whose K -rational points classify isomorphism classes of pairs (E, C) , where E/K is an elliptic curve and C is a cyclic ($\text{Gal}(\bar{K}/K)$ -invariant) subgroup of E . Let $X_0(n)$ be the compactification of $Y_0(n)$.

Recall that a \mathbb{Q} -curve is an elliptic curve E/K over a number field, such that it is $\bar{\mathbb{Q}}$ -isogenous to all of its $\text{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ -conjugates.

For computations we use Magma [1].

3. TORSION OF RATIONAL ELLIPTIC CURVES OVER QUADRATIC FIELDS

The results of this short section will be needed in the proof of Theorem 1, but are also interesting in their own right. They also provide a nice introductory exercise for the much harder cubic fields case.

Theorem 2. *Let E be a rational elliptic curve and F a quadratic field.*

a) *The torsion of $E(F)$ is isomorphic to one of the following groups*

$$(5) \quad \begin{aligned} &\mathbb{Z}/m\mathbb{Z}, \quad m = 1, \dots, 10, 12, 15, 16 \\ &\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2m\mathbb{Z}, \quad 1 \leq m \leq 6. \\ &\mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/3m\mathbb{Z}, \quad m = 1, 2, \\ &\mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}. \end{aligned}$$

b) *Each of these groups, except for $\mathbb{Z}/15\mathbb{Z}$, appears as the torsion structure over a quadratic field for infinitely many rational elliptic curves E .*

- c) *The elliptic curves 50B1 and 50A3 have 15-torsion over $\mathbb{Q}(\sqrt{5})$, 50B2 and 450B4 have 15-torsion over $\mathbb{Q}(\sqrt{-15})$. These are the only rational curves having non-trivial 15-torsion over any quadratic field.*

Remark 3. a) The elliptic curves 50B1 and 50A3 are twists by 5 of each other, and hence become isomorphic over $\mathbb{Q}(\sqrt{5})$. Similarly, 50B2 and 450B4 are twists of each other by -15 and become isomorphic over $\mathbb{Q}(\sqrt{-15})$.

- b) These elliptic curves are "exceptional curves", in the sense that they are the only elliptic curves (not just rational) over the respective quadratic fields with 15-torsion (see [17, 34] for details).

Before we proceed with the proof of Theorem 2, we will prove the following lemma.

Lemma 4. *Let E be a rational elliptic curve. Then in the family of all quadratic twists E^d of E (including E itself) there is at most one elliptic curve with nontrivial n -torsion for $n = 5, 7$, and at most 2 curves with 3-torsion.*

Proof. We will often use the fact (see for example [14, Theorem 3 and Corollary 4]) that if $F = \mathbb{Q}(\sqrt{d})$, and n an odd integer > 1 then

$$(6) \quad E(F)[n] = E(\mathbb{Q})[n] \oplus E^d(\mathbb{Q})[n].$$

Suppose that two twists E^d and $E^{d'}$ of E have non-trivial n -torsion, for $n = 5$ or 7 . Then $E^{d'}$ is a twist of E^d by d'/d and now (6) implies that $E^d(\mathbb{Q}(\sqrt{d/d'}))$ has full n -torsion, which is impossible.

It is impossible that E has 3 twists with 3-torsion, as this would imply that, by [8, Lemma 9], $E^d(F_2)$ would contain $(\mathbb{Z}/3\mathbb{Z})^3$ for some twist E^d of E and some biquadratic extension F_2 of \mathbb{Q} . \square

Proof of Theorem 2. The possible torsion structures of a rational elliptic curve over a quadratic field is obviously a subset of the list (2). The equality (6) rules out the possibility of n -torsion for $n = 11, 13$. Note that the number of points of order 2 over F on an elliptic curve

$$E : y^2 = f(x) = x^3 + ax + b$$

is equal to the number of roots of f over F . It follows that if $E(\mathbb{Q})$ has no 2-torsion, then neither does $E(F)$.

Suppose $E(F)$ had $2n$ -torsion, for $n = 7$ or 9 . Then, as noted above, both $E(\mathbb{Q})$ and $E^d(\mathbb{Q})$ would have a 2-torsion point, and by (6) it would follow that either $E(\mathbb{Q})$ or $E^d(\mathbb{Q})$ has a point of order n and therefore also a point of order $2n$, which is impossible by Mazur's theorem.

It can be seen from [12, Theorems 3.2., 3.3., 3.4., 3.5. and 3.6.] that there exist infinitely many rational elliptic curves with torsion $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/10\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/12\mathbb{Z}$, $\mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$, $\mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/6\mathbb{Z}$ and $\mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$.

In [24, Remark 2.6. (d)] one is given a construction which can be used to construct infinitely many rational elliptic curves with 16-torsion over quadratic fields.

Finally, we wish to find all rational elliptic curves with 15-torsion over quadratic fields. Let E/\mathbb{Q} be an elliptic curve which attains 15-torsion over a quadratic field. By (6) this implies that,

$$(7) \quad E(\mathbb{Q})_{tors} \simeq \mathbb{Z}/3\mathbb{Z} \text{ and } E^d(\mathbb{Q})_{tors} \simeq \mathbb{Z}/5\mathbb{Z}$$

or vice versa. Suppose without loss of generality that it is as in (7). It also follows, since if E has a p -isogeny, so do all the quadratic twists E^d of E , that E has to have a 15-isogeny. But there are only 4 families of twists of rational elliptic curves with a 15-isogeny [30, p.78–80], those with j -invariants

$$-25/2, -349938025/8, -121945/32, 46969655/32768,$$

which are the twists of the elliptic curves 50A1, 50A2, 50B1 and 50B2, respectively.

By the division polynomial method we find that 50B1 has 15-torsion only over one quadratic field, namely $\mathbb{Q}(\sqrt{5})$, that 50B2 has 15-torsion only over one quadratic field, namely $\mathbb{Q}(\sqrt{-15})$, and that 50A1 and 50A2 have no twists with 5-torsion, completing the proof of the theorem. \square

4. AUXILIARY RESULTS

In this section we prove a series of results that we will need for the proof of Theorem 1.

Lemma 5. *Let F/\mathbb{Q} be a quadratic extension, n an odd positive integer, and E/\mathbb{Q} an elliptic curve such that $E(F)$ contains $\mathbb{Z}/n\mathbb{Z}$. Then E/\mathbb{Q} has an n -isogeny.*

Proof. Factor n as $n = \prod_{i=1}^k p_i^{e_i}$, where p_i and p_j are distinct primes for $i \neq j$. As already mentioned in (6), if $F = \mathbb{Q}(\sqrt{d})$, then for each $i = 1, \dots, k$

$$E(F)[p_i^{e_i}] = E(\mathbb{Q})[p_i^{e_i}] \oplus E^d(\mathbb{Q})[p_i^{e_i}].$$

Thus either $E(\mathbb{Q})$ or $E^d(\mathbb{Q})$ has a point of order $p_i^{e_i}$ and thus a $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -invariant subgroup generated by this point. If an elliptic curve has a $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -invariant cyclic subgroup of order $p_i^{e_i}$, then so does every twist of E and hence we conclude that E has a $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -invariant cyclic subgroup of order n , proving the lemma. \square

We will also extensively use the well-known classification of possible degrees of cyclic isogenies over \mathbb{Q} .

Theorem 6 ([27, 19, 20, 21]). *Let E/\mathbb{Q} be an elliptic curve with an n -isogeny. Then $n \leq 19$ or $n \in \{21, 25, 27, 37, 43, 67, 163\}$. If E does not have complex multiplication, then $n \leq 18$ or $n \in \{21, 25, 37\}$.*

Next we show that from 2 independent isogenies of degrees m and n on an elliptic curve E , one can deduce the existence of a mn -isogeny on an isogenous curve E' .

Lemma 7. *Let E/F be an elliptic curve over a number field with 2 independent isogenies (the intersection of their kernels is trivial) of degrees m and n (over F). Then E is isogenous (over F) to an elliptic curve E'/F with an mn -isogeny.*

Proof. Suppose E has an m -isogeny $f : E \rightarrow E'$ and an n -isogeny $g : E \rightarrow E''$. We claim that $h = g \circ \hat{f} : E' \rightarrow E''$, where \hat{f} is the dual isogeny of f , is a cyclic mn -isogeny.

Suppose the opposite, that h is not cyclic. Then for some integer $l \geq 2$ which divides both m and n , $E'[l] \subset \ker h$. Note that

$$\hat{f}(E'[l]) \simeq \mathbb{Z}/l\mathbb{Z} \text{ and } \hat{f}(E'[l]) \subset \ker f$$

since $f \circ \hat{f} = [n]_{E'}$. But since $\hat{f}(E'[l])$ contains non-zero points and $\ker g$ and $\ker f$ have trivial intersection, this means that g cannot send $\hat{f}(E'[l])$ to 0. Therefore $h(E'[l]) \neq 0$, which is a contradiction. \square

The following four results will be useful in controlling the 2-primary torsion of rational elliptic curves over cubic fields.

Lemma 8 ([34, Lemma 1]). *If $E(\mathbb{Q})$ has a nontrivial 2-Sylow subgroup, $E(K)$ has the same 2-Sylow subgroup as $E(\mathbb{Q})$.*

Proposition 9. *Let $M \neq \mathbb{Q}(i)$, and let E/\mathbb{Q} be an elliptic curve such that $E(M)[2] = 0$. Then the 2-Sylow subgroup of $E(L)$ is either trivial or $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$.*

Proof. Suppose $E(L)[2] \neq 0$. Write

$$E : y^2 = f(x) = x^3 + ax + b,$$

where $f(x)$ is irreducible over M . As L/M is Galois, it follows that since f has one root over L , all the roots of f are defined over L . Hence $E(L)[2] \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$.

Suppose that $E(L)$ has a point of order 4. As L does not contain i , it follows that the only possibility for $E(L)$ to have a 4-torsion point is that $E(L)[4] \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$.

We now prove that a group of order 3 has to fix a line of $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$. Let $G := \text{Gal}(L/M)$. We have the short exact sequence

$$(8) \quad 0 \rightarrow E(L)[2] \rightarrow E(L)[4] \rightarrow E(L)[4]/E(L)[2] \rightarrow 0$$

and it follows that

$$(9) \quad 0 \rightarrow E(L)[2]^G \rightarrow E(L)[4]^G \rightarrow (E(L)[4]/E(L)[2])^G \rightarrow H^1(G, E(L)[2])$$

It is easy to compute that $H^1(G, E(L)[2]) = 0$, and since $E(L)[4]/E(L)[2]$ is a group of order 2, it follows that

$$(E(L)[4]/E(L)[2])^G \simeq \mathbb{Z}/2\mathbb{Z},$$

from which we conclude that $E(L)[4]^G \neq 0$. We conclude that $E(M)$ has a 2-torsion point, which is a contradiction. \square

Proposition 10. *Let $M = \mathbb{Q}(i)$. Let E/\mathbb{Q} be an elliptic curve with no \mathbb{Q} -rational points of order 2. Then*

- a) *If $E(K)$ has a point of order 4, then $\Delta(E) \in -1 \cdot (\mathbb{Q}^*)^2$, $j(E) = -4t^3(t+8)$ for some $t \in \mathbb{Q}$ and $E(L)[4] \simeq \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$.*
- b) *$E(K)$ has no points of order 8.*

Proof. First note that from the assumption that $E(\mathbb{Q})[2] = 0$, it follows that $E(\mathbb{Q}(i))[2] = 0$. Suppose $E(L)[2] \neq 0$. Since $L/\mathbb{Q}(i)$ is Galois, it follows that $E(L)[2] \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$.

If $E(L)$ has a point of order 4, by the same argument as in the proof of Proposition 9 it follows that $E(L)[4]$ cannot be $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$. Thus

$$E(L)[4] \simeq \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z},$$

and $\mathbb{Q}(E[2]) = \mathbb{Q}(E[4])$. Note that for any elliptic curve E' , the field $\mathbb{Q}(E'[2])$ contains $\mathbb{Q}(\sqrt{\Delta})$ and $\mathbb{Q}(E'[4])$ contains $\mathbb{Q}(i)$, and since $\mathbb{Q}(E[2])$ is a S_3 extension of E , it follows that Δ is a square in $\mathbb{Q}(i)$, but not in \mathbb{Q} , i.e. $\Delta(E) \in -1 \cdot (\mathbb{Q}^*)^2$.

By [6, Lemma], since $\text{Gal}(\mathbb{Q}(E[4])/\mathbb{Q}) \simeq S_3$, which is isomorphic to a subgroup of $H_{24} = \mathbb{Z}/3\mathbb{Z} \rtimes D_8$, it follows that $j(E) = -4t^3(t+8)$ for some $t \in \mathbb{Q}$. This concludes the proof of a).

Suppose now $E(K)$ has a point of order 8. It follows that $E(L)[8] \simeq \mathbb{Z}/4\mathbb{Z} \oplus \mathbb{Z}/8\mathbb{Z}$. Let $G := \text{Gal}(L/M)$ and take the short exact sequence

$$(10) \quad 0 \rightarrow E(L)[2] \rightarrow E(L)[8] \rightarrow E(L)[8]/E(L)[2] \rightarrow 0.$$

It follows that

$$(11) \quad 0 \rightarrow E(L)[2]^G \rightarrow E(L)[8]^G \rightarrow (E(L)[8]/E(L)[2])^G \rightarrow H^1(G, E(L)[2]).$$

Note that $E(L)[8]/E(L)[2] \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$ and since we have shown in the proof of Proposition 9 that $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$ has a G -invariant line, it follows that $(E(L)[8]/E(L)[2])^G \neq 0$. Now from the fact that $H^1(G, E(L)[2]) = 0$ it follows that $E(L)[8]^G \neq 0$, from which it follows $E(M)[2] \neq 0$, which is a contradiction. \square

Remark 11. Note that there exist elliptic curves such that $\mathbb{Q}(E[2]) = \mathbb{Q}(E[4])$ and

$$\text{Gal}(\mathbb{Q}(E[2])/\mathbb{Q}) \simeq \text{Gal}(\mathbb{Q}(E[4])/\mathbb{Q}) \simeq S_3.$$

The elliptic curve 1936D1 is such a curve.

We can combine Propositions 9 and 10 into the following corollary.

Corollary 12. *Let E/\mathbb{Q} be an elliptic curve such that $E(\mathbb{Q})$ has no points of order 4. Then $E(K)$ has no 8-torsion and has a point of order 4 only if*

$E(\mathbb{Q})[2] = 0$, $M = \mathbb{Q}(i)$, $\Delta(E) \in -1 \cdot (\mathbb{Q}^*)^2$, and $j(E) = -4t^3(t+8)$ for some $t \in \mathbb{Q}$.

Proof. If $E(\mathbb{Q})$ has a 2-torsion point, the statement follows from Lemma 8.

If $E(\mathbb{Q})$ has no 2-torsion, the statement follows from Propositions 9 and 10. \square

The next step towards the proof of Theorem 1 is to control the growth of the 3-torsion, for which the following two propositions will be useful.

Lemma 13. *If $E(M)$ does not have a point of order 3, neither does $E(L)$.*

Proof. Let $G = \text{Gal}(L/M)$. Then $E(L)[3]$ is \mathbb{F}_3 -linear representation of G . Thus if $E(L)[3] \neq 0$, then $E(L)[3]^G = E(M)[3] \neq 0$ by [39, Proposition 26, p.64.]. \square

Proposition 14. *Suppose $E(K)$ has a point of order 9. Then E/\mathbb{Q} has an isogeny of degree 9 or 2 independent isogenies of degree 3.*

Proof. Suppose the opposite, that E/\mathbb{Q} does not have an isogeny of degree 9 nor 2 independent isogenies of degree 3. Let $\langle \sigma \rangle = \text{Gal}(L/M)$, $\langle \tau \rangle = \text{Gal}(L/K)$ and $P \in E(K)$ be a point of order 9. It is easy to see that $E(L)$ has a 9-torsion point, and that $E(M)$ has a point of order 3 by Lemma 13. Also, $E(M)$ cannot have a point of order 9, since this would imply that E/\mathbb{Q} has a 9-isogeny by Lemma 5, which would contradict our assumption.

We examine how σ acts on P . Let $E[9] = \langle P, Q \rangle$ and $P^\sigma = \alpha P + \beta Q$.

Suppose $\beta = 0$. Then σ fixes $\langle P \rangle$ and since P is a K -rational point, τ also fixes $\langle P \rangle$. Since σ and τ generate $\text{Gal}(L/\mathbb{Q})$, it follows that that E/\mathbb{Q} has a 9-isogeny, contradicting our assumption.

Note that $P^\sigma \in E(L)$ so $(9 - \alpha)P + P^\sigma = \beta Q \in E(L)$, and it follows that β has to be 3 or 6, otherwise the full 9-torsion would be defined over L , which would further imply that $L = \mathbb{Q}(\zeta_9)$, which is impossible since $\text{Gal}(L/\mathbb{Q}) \simeq \mathbb{Z}/3\mathbb{Z}$ or S_3 and $\text{Gal}(\mathbb{Q}(\zeta_9)/\mathbb{Q}) \simeq \mathbb{Z}/6\mathbb{Z}$. Furthermore, it follows that $E(L)[9] \simeq \mathbb{Z}/3\mathbb{Z} \oplus \mathbb{Z}/9\mathbb{Z}$ and from this $M = \mathbb{Q}(\sqrt{-3})$.

Let $E[3] = \langle P', Q' \rangle$. By Lemma 13, $E(M)$ has non-trivial 3-torsion; suppose $P' \in E(M)$. Now $G = \text{Gal}(L/M)$ acts on $\langle Q' \rangle$, and since G is a group of order 3, it follows that $\langle Q' \rangle^G = \langle Q' \rangle$ and hence $E(M)$ has full 3-torsion. Since $M = \mathbb{Q}(\sqrt{-3})$, it holds that $E(M)[3] = E(\mathbb{Q})[3] \oplus E^{-3}(\mathbb{Q})[3]$ by (6), and since an elliptic curve over \mathbb{Q} cannot have full 3-torsion, it follows that $E(\mathbb{Q})[3] \simeq \mathbb{Z}/3\mathbb{Z}$. Suppose without loss of generality that $P' \in E(\mathbb{Q})$. Then $\langle P' \rangle$ is obviously a $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -invariant subgroup and we will show that there exists another orthogonal to it. Let $\langle \mu \rangle = \text{Gal}(M/\mathbb{Q})$. Then

$$Q'^\mu = \alpha P' + \beta Q',$$

$$Q'^{\mu^2} = Q' = \alpha(1 + \beta)P' + \beta^2 Q',$$

where $\alpha, \beta \in \{0, 1, 2\}$. It follows that $\beta = 1$ or 2 . If $\beta = 1$ then $\alpha = 0$, which would imply that $E(\mathbb{Q})$ has full 3-torsion, which is impossible. Hence $\beta = 2$

and $\langle Q' + 2\alpha P' \rangle$ is a $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -invariant subgroup orthogonal to $\langle P' \rangle$, which shows that E has 2 independent 3-isogenies, giving a contradiction. \square

We now move to the study of the p -torsion of $E(K)$ for $p > 3$.

Lemma 15. *For $p > 3$ prime, $E(L)[p] = 0$ or $\mathbb{Z}/p\mathbb{Z}$.*

Proof. This follows from the fact that $E(L)[p] \simeq \mathbb{Z}/p\mathbb{Z} \oplus \mathbb{Z}/p\mathbb{Z}$ would, by the existence of the Weil pairing, require the p -th cyclotomic field $\mathbb{Q}(\zeta_p)$ to be contained in L , which is impossible. \square

Next we study for which p , $E(M)[p] = 0$ implies $E(L)[p] = 0$. We prove a more general statement, that applies beyond the case of cubic extensions.

Lemma 16. *Let p, q be odd distinct primes, F_2/F_1 a Galois extension of number fields such that $\text{Gal}(F_2/F_1) \simeq \mathbb{Z}/q\mathbb{Z}$, and E/F_1 an elliptic curve with no p -torsion over F_1 . Then if q does not divide $p - 1$ and $\mathbb{Q}(\zeta_p) \not\subset F_2$, then $E(F_2)[p] = 0$.*

Proof. Since if one point of order p is defined over F_2 , then so are all its multiples, it follows that either $p - 1$ or $p^2 - 1$ points of order p are defined over F_2 , but not over F_1 . But it is impossible that all $p^2 - 1$ appear because of $\mathbb{Q}(\zeta_p) \not\subset F_2$.

Let $\langle \sigma \rangle = \text{Gal}(F_2/F_1)$, P be a point of order p in $E(F_2)$ and then note that $P^\sigma \neq P$, and that $\text{Gal}(F_2/F_1)$ acts on $\langle P \rangle$. We have a homomorphism

$$\mathbb{Z}/q\mathbb{Z} \simeq \text{Gal}(F_2/F_1) \rightarrow \text{Aut}(\langle P \rangle) \simeq \text{Aut}(\mathbb{Z}/p\mathbb{Z}) \simeq (\mathbb{Z}/p\mathbb{Z})^\times,$$

so either $\text{Gal}(F_2/F_1)$ acts trivially on P and therefore $P \in E(F_1)[p]$ or q divides $p - 1$. \square

In this paper we will use only the special case $q = 3$, $F_1 = M$ and $F_2 = L$ of Lemma 16. We also need to show the non-existence of points of order p^2 in $E(L)$. Again, we prove a more general statement.

Lemma 17. *Let p be an odd prime number, q a prime not dividing p , F_2/F_1 a Galois extension of number fields such that $\text{Gal}(F_2/F_1) \simeq \mathbb{Z}/q\mathbb{Z}$, E/F_1 an elliptic curve, and suppose $E(F_1) \supset \mathbb{Z}/p\mathbb{Z}$, $E(F_1) \not\supset \mathbb{Z}/p^2\mathbb{Z}$ and $\zeta_p \notin F_2$. Then $E(F_2) \not\supset \mathbb{Z}/p^2\mathbb{Z}$.*

Proof. Suppose $\mathbb{Z}/p^2\mathbb{Z} \subset E(F_2)$. By the assumption $\zeta_p \notin F_2$ and the existence of the Weil pairing, it follows that $E(F_2)[p^2] \simeq \mathbb{Z}/p^2\mathbb{Z}$. Let $P \in E(F_1)$ be of order p and $\langle \sigma \rangle = \text{Gal}(F_2/F_1)$. Let

$$S = \{Q \in E(F_2) \mid pQ = P\}.$$

The set S has p elements, on which $\text{Gal}(F_2/F_1)$ acts. By the Orbit Stabilizer Theorem, the orbits under the action of $\text{Gal}(F_2/F_1)$ have to have length q , since if a point in S was left fixed, it would mean that it is F_1 -rational. This implies that S decomposes into orbits of q elements each, which is a contradiction with our assumption that q does not divide p . \square

We will again use Lemma 17 only in the special case $q = 3$, $F_1 = M$ and $F_2 = L$. For n coprime to 6, the existence of a point of order n in $E(K)$ will imply the existence of an n -isogeny over \mathbb{Q} , as the following lemma shows.

Lemma 18. *Let n be an odd integer not divisible by 3 and suppose $E(K)$ has a point of order n . Then E/\mathbb{Q} has an isogeny of degree n .*

Proof. First note that $E(L)$ has a point P of order n . Let

$$\langle \sigma \rangle = \text{Gal}(L/M), \quad \langle \tau \rangle = \text{Gal}(L/K), \quad \langle \sigma, \tau \rangle = \text{Gal}(L/\mathbb{Q}).$$

As P is K -rational, it follows that $P^\tau = P$. Let $E[n] = \langle P, Q \rangle$ and $P^\sigma = \alpha P + \beta Q \in E(L)$. We have $(n - \alpha)P + P^\sigma = \beta Q \in E(L)$. If $\beta \not\equiv 0 \pmod{n}$ then βQ is a point of order $l|n$ not contained in $\langle P \rangle$, from which it follows that $E(L)$ has full l -torsion, which is impossible by Lemma 15. We conclude that $\beta \equiv 0 \pmod{n}$.

Hence

$$P^\mu = kP \text{ for all } \mu \in \text{Gal}(L/\mathbb{Q}),$$

and since the action of $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ on $\langle P \rangle$ factors through $\text{Gal}(L/\mathbb{Q})$, it follows that

$$P^\mu = kP \text{ for all } \mu \in \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}),$$

which means that E/\mathbb{Q} has an n -isogeny. \square

In the special case when $K = L$, the conclusion of Lemma 18 follows when n is a multiple of 3.

Lemma 19. *Suppose $K = L$, i.e. K/\mathbb{Q} is a Galois extension. Let n be an odd integer and suppose $E(K)$ has a point of order n . Then E/\mathbb{Q} has an isogeny of degree n .*

Proof. The proof follows by a similar argument as in Lemma 18 and by using the fact that $\mathbb{Q}(\zeta_k)$ is not contained in K , for any divisor $k \geq 3$ of n . \square

5. PROOF OF THEOREM 1

We are now ready to prove Theorem 1, which we will do in a series of Lemmas and Propositions. Recall that if a point in $E(K)$ has prime order p , then $p \leq 13$ (see [36, 37]).

Lemma 20. *The 3-Sylow subgroup of $E(K)$ is isomorphic to a subgroup of $\mathbb{Z}/9\mathbb{Z}$.*

Proof. This follows by [31, Theorem (4.1)] and by the existence of the Weil pairing. \square

Lemma 21. *The 5-Sylow groups of $E(\mathbb{Q})$ and $E(K)$ are equal.*

Proof. First note that $E(L)$ cannot have full 5-torsion by Lemma 15.

Suppose $E(\mathbb{Q})[5] \simeq \mathbb{Z}/5\mathbb{Z}$. Then $E(M) \simeq \mathbb{Z}/5\mathbb{Z}$ and Lemma 17 shows that $E(L)$ cannot have a point of order 25, and hence the 5-Sylow groups

of $E(\mathbb{Q})$ and $E(L)$ (and hence also $E(K)$) are equal and all isomorphic to $\mathbb{Z}/5\mathbb{Z}$.

Suppose $E(\mathbb{Q})[5] = 0$. If $E(M)[5] = 0$, then $E(L)[5] = 0$ (and hence $E(K)[5] = 0$) by Lemma 16. If $E(M)[5] \simeq \mathbb{Z}/5\mathbb{Z}$, then $0 = E(\mathbb{Q})[5] = E(M)[5] \cap E(K)[5]$, from which it follows that $E(K)[5] = 0$ (note that $E(K)$ here cannot have a 5-torsion point that is not in $E(M)$ because then $E(L)$ would have full 5-torsion). \square

Lemma 22. *There are no points of order 11 in $E(K)$.*

Proof. By Lemma 16, $E(L)$ has 11-torsion only if $E(M)$ has 11-torsion, which is never true, as rational elliptic curves cannot have 11-torsion over \mathbb{Q} or over a quadratic field, by Theorem 2. Hence $E(K)$ has no 11-torsion. \square

Lemma 23. *$E(K)$ has no points of order 35, 49, 65, 91 or 169.*

Proof. This follows by Lemma 18 and Theorem 6. \square

Lemma 24. *There exists no rational elliptic curves with points of order 15 or 16 over a cubic field.*

Proof. As $E(L)[5] = E(M)[5]$ and $E(M)[3] = 0 \implies E(L)[3] = 0$ by Lemmas 16 and 13, it follows that the only way for $E(L)$ to have 15-torsion is for $E(M)$ to have 15-torsion.

It follows that, by Theorem 2 c), E is 50B1, 50B2, 50A3 or 450B4. By the division polynomial method, we find that none of these curves have points of order 15 over any cubic field.

If $E(\mathbb{Q})$ has a non-trivial 2-Sylow group, then the 2-Sylow subgroups of $E(\mathbb{Q})$ and $E(K)$ are equal by Lemma 8 and hence $E(K)$ has no points of order 16. If the 2-Sylow subgroup of $E(\mathbb{Q})$ is trivial, then by Corollary 12, $E(K)$ has no points of order 8. \square

Proposition 25. *The elliptic curve 162B1 has torsion isomorphic to $\mathbb{Z}/21\mathbb{Z}$ over $\mathbb{Q}(\zeta_9)^+$. This is the unique pair (E, K) of a rational elliptic curve E and a cubic field such that $E(K)$ has a point of order 21.*

Proof. By Lemma 13, if $E(M)_{tors} = 0$, or $\mathbb{Z}/7\mathbb{Z}$, then $E(L)[3] = 0$. Suppose now that $E(K)[21] \supset \mathbb{Z}/21\mathbb{Z}$. By Lemma 18, it follows that E/\mathbb{Q} has an isogeny of degree 7, and since it has a 3-torsion point, it also has a 21-isogeny. There are 4 curves (up to $\overline{\mathbb{Q}}$ -isomorphism) with a 21-isogeny [30, p.78–80]. These are the curves in the 162B or 162C isogeny classes. Note that the 162B isogeny class is a -3 twist of the 162C class.

By the division polynomial method we find that the only twists of the curves in the 162B and 162C isogeny classes with non-trivial 3-torsion are the curves 162C1, 162C3, 162B1 and 162B3. By the division polynomial method, we find that only 162B1 has a 7-torsion point over a cubic field, the field $\mathbb{Q}(\zeta_9)^+$, which is generated by $x^3 - 3x^2 + 3$. \square

Note that since 162B1 is the unique curve with 21-torsion over any cubic field and since it has torsion exactly $\mathbb{Z}/21\mathbb{Z}$, this means that there exist no points of order $21n$ on rational elliptic curves over cubic fields, for any integer $n \geq 2$.

Remark 26. Note that in [34, Remark 2] we misstated that from the fact that

$$(12) \quad X_0(21)(\mathbb{Q}(\zeta_9)^+) = X_0(21)(\mathbb{Q})$$

(note that $K_7 = \mathbb{Q}(\zeta_9)^+$, using the notation of [34]) one can conclude that there are no elliptic curves with 21-torsion over $\mathbb{Q}(\zeta_9)^+$, while what should have been written is that from (12) we can determine whether 21-torsion appears over $\mathbb{Q}(\zeta_9)^+$ by checking whether twists of rational elliptic curves with rational 21-isogeny have 21-torsion over $\mathbb{Q}(\zeta_9)^+$. The point of the remark, that if we could find out whether $Y_1(25)(\mathbb{Q}(\zeta_9)^+) = \emptyset$, then we could completely classify the possible torsion groups of elliptic curves over $\mathbb{Q}(\zeta_9)^+$, remains true.

Lemma 27. $E(K)$ does not have points of order 20, 24, 26, 28, 36 or 39.

Proof. Suppose $E(K)$ has a 20-torsion point. Then $E(M)$ has to have a 5-torsion point by Lemma 16, and by (6) either $E^d(\mathbb{Q})$ or $E(\mathbb{Q})$ has a 5-torsion point, where $M = \mathbb{Q}(\sqrt{d})$. We can suppose without loss of generality that $E(\mathbb{Q})$ has a 5-torsion point, otherwise we proceed with the proof using E^d instead of E .

Thus, by [23, Table 3.], E/\mathbb{Q} has a model

$$(13) \quad E : y^2 + (1-t)xy - ty = x^3 - tx^2 \text{ for some } t \in \mathbb{Q}^*.$$

If $E(\mathbb{Q})$ had a 4-torsion point, it would follow that it has a 20-torsion point which is impossible. Thus by Corollary 12, it follows that $E(\mathbb{Q})[2] = 0$ and $\Delta(E) = -k^2$ for some $k \in \mathbb{Q}^*$. Hence

$$-k^2 = \Delta(E) = t^5(t^2 - 11t - 1)$$

for some $t \in \mathbb{Q}^*$, which is equivalent to

$$X : y^2 = t^3 + 11t^2 - t$$

having rational points with $t \in \mathbb{Q}^*$. But $X(\mathbb{Q}) = \{0, (0, 0)\}$.

If $E(K)$ had a 24-torsion point, then Corollary 12 would imply that $E(\mathbb{Q})$ has a non-trivial 2-Sylow group, and from this fact and Lemma 8 it follows that $E(\mathbb{Q})$ has a point of order 8. By Lemma 13, $E(M)$ has 3-torsion point and hence a 24-torsion point which is in contradiction with Theorem 2, since M/\mathbb{Q} is quadratic.

Suppose $E(K) \supset \mathbb{Z}/26\mathbb{Z}$. It follows by Lemma 18 that E/\mathbb{Q} has an isogeny of degree 13, and this implies that $E(\mathbb{Q})[2] = 0$, since by Theorem 6 there are no elliptic curves with 26-isogenies over \mathbb{Q} . Because E has a

13-isogeny, but no 13-torsion over \mathbb{Q} , it follows that $\mathbb{Q}(\langle P \rangle)/\mathbb{Q}$ is Galois and non-trivial. Since this is contained in K and K is of prime degree, we must have $\mathbb{Q}(\langle P \rangle) = K$ and therefore K/\mathbb{Q} is Galois.

From the facts that K/\mathbb{Q} is cubic and Galois, $E(\mathbb{Q})[2] = 0$ and $E(K)[2] \neq 0$, it follows that $E(K)$ has full 2-torsion and hence $E(K) \supset \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/26\mathbb{Z}$.

By [18, 29] an elliptic curve with a 13-isogeny over \mathbb{Q} has j -invariant

$$j = \frac{(t^2 + 5t + 13)(t^4 + 7t^3 + 20t^2 + 19t + 1)^3}{t}, \quad t \in \mathbb{Q}^\times.$$

It follows that E is a quadratic twist of an elliptic curve E_0 with discriminant

$$\begin{aligned} \Delta(E_0) &= t(t^2 + 5t + 13)^2(t^4 + 7t^3 + 20t^2 + 19t + 1)^6(t^2 + 6t + 13)^9 \\ &\quad \times (t^6 + 10t^5 + 46t^4 + 108t^3 + 122t^2 + 38t - 1)^6, \end{aligned}$$

and thus $\Delta(E) = u^{12}\Delta(E_0)$ for some $u \in \mathbb{Q}^\times$. The curve E gains full 2-torsion over a cubic field only if $\Delta(E)$ is a square which happens only if

$$X : y^2 = x(x^2 + 6x + 13) \text{ for some } x, y \in \mathbb{Q}^\times$$

has solutions. But $X(\mathbb{Q}) = \{0, (0, 0)\}$, and hence that is impossible.

Suppose $E(K)$ has a 28-torsion point. It follows that E/\mathbb{Q} has a 7-isogeny by Lemma 18. If $E(\mathbb{Q})$ had a 4-torsion point, this would imply that E/\mathbb{Q} has a 28-isogeny, which is impossible by Theorem 6. Thus $E(\mathbb{Q})$ does not have a 4-torsion point and by Corollary 12 it follows that K is not a Galois extension of \mathbb{Q} and $\Delta(E) = -k^2$, for some $k \in \mathbb{Q}^*$.

Note that since E cannot have 2 independent rational 7-isogenies (see [23, Proposition III.2.1.]), it follows that the kernel of the rational 7-isogeny is equal to $E(K)[7]$. As the points in the kernel of the rational 7-isogeny are defined over a Galois extension of \mathbb{Q} , it follows that they must be defined already over \mathbb{Q} , since they cannot be K -rational but not \mathbb{Q} -rational (because K/\mathbb{Q} is not Galois).

Hence $E(\mathbb{Q})$ has points of order 7, and by [23, Table 3.], it follows that E is of the form

$$(14) \quad E : y^2 + (-t^2 + t + 1)xy + (-t^3 + t^2)y = x^3 + (-t^3 + t^2)x^2, \text{ for some } t \in \mathbb{Q}, t \notin \{0, 1\}.$$

and that

$$-k^2 = \Delta(E) = t^7(t-1)^7(t^3 - 8t^2 + 5t - 1),$$

which is equivalent to

$$X : y^2 = t(t+1)(t^3 + 8t^2 + 5t + 1),$$

having rational points such that $t \notin \{0, -1\}$. But the Jacobian J of X has rank 0 over \mathbb{Q} and it is an easy computation in Magma (using the Chabauty0 function) to show that

$$X(\mathbb{Q}) = \{\infty, (0, 0), (-1, 0)\},$$

and thus completing the proof that there are no rational elliptic curves with 28-torsion over a cubic field.

Suppose $E(K)$ has a 36-torsion point. This implies that, by Corollary 12, $E(\mathbb{Q})$ has either a point of order 4 or no 2-torsion. Also, by Proposition 14, E/\mathbb{Q} has to have a 9-isogeny or 2 independent isogenies of degree 3.

Suppose first that $E(\mathbb{Q})$ has a 4-torsion point. If E/\mathbb{Q} had a 9-isogeny, this would imply, by Lemma 7 that E/\mathbb{Q} is isogenous to a rational curve which has a 36-isogeny, which is impossible by Theorem 6. On the other hand, by [23, Main Result 2.], an elliptic curve with 2 independent 3-isogenies cannot have a 4-torsion point.

Suppose now that $E(\mathbb{Q})$ has no 2-torsion. We split this case into 2 sub-cases: when $E(\mathbb{Q})$ has a rational 9-isogeny, and when E has 2 independent rational isogenies of degree 3.

Suppose E has a 9-isogeny. Then, by [23, 15], E is a twist of an elliptic curve E_0 with j -invariant

$$(15) \quad j = \frac{t^{12} - 72t^9 + 1728t^6 - 13824t^3}{t^3 - 27}, \quad t \in \mathbb{Q} \setminus \{0, 3\}$$

and

$$\Delta(E_0) = 2^{12}3^6(t^3 - 27),$$

and since E has to be a twist of E_0 , it follows that $\Delta(E) = u^{12}\Delta(E_0)$, for some $u \in \mathbb{Q}^\times$. By Corollary 12, the curve E gains a 4-torsion point over a cubic field only if $-y^2 = \Delta(E) \neq 0$ has solutions, which is equivalent to

$$X : y^2 = t^3 + 27, \quad t \in \mathbb{Q} \setminus \{0, -3\}, y \in \mathbb{Q}$$

having a solution. But $X(\mathbb{Q}) = \{0, (-3, 0)\}$.

Suppose now that E has 2 independent rational 3-isogenies and that E gains a point of order 9 over K . By the same type of argument as in the proof of Proposition 14, it follows that $M = \mathbb{Q}(\sqrt{-3})$. Since E has no rational 4-torsion, but has a 4-torsion point over K , by Corollary 12, it follows that $M = \mathbb{Q}(i)$, which is a contradiction.

If $E(K)$ had a 39-torsion point, this would imply that $E(M)$ has a 3-torsion point by Lemma 13, from which it would follow, by Lemma 5, that E/\mathbb{Q} has a 3-isogeny. Also, E/\mathbb{Q} would have a 13-isogeny by Lemma 18. But this would imply that there is an elliptic curve over \mathbb{Q} with a 39-isogeny by Lemma 7, which is impossible by Theorem 6. \square

Lemma 28. *$E(K)$ cannot have subgroups isomorphic to $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/10\mathbb{Z}$, $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/12\mathbb{Z}$ or $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/18\mathbb{Z}$.*

Proof. Suppose $E(K) \supset \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/10\mathbb{Z}$. By Lemma 16, this implies that $E(\mathbb{Q})$ has a 5-torsion point. This implies, by [23, Table 3.], that E has a model as in (13). Since $E(\mathbb{Q})$ cannot contain $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/10\mathbb{Z}$, either $E(\mathbb{Q})[2] = 0$ or $\mathbb{Z}/2\mathbb{Z}$. But if $E(\mathbb{Q})[2] = \mathbb{Z}/2\mathbb{Z}$, then E would gain full 2-torsion over a

quadratic instead of a cubic field. We conclude that $E(\mathbb{Q})[2] = 0$, and that E gains full 2-torsion over the cubic field K . This happens if and only if the discriminant $\Delta(E)$ is a square in \mathbb{Q}^\times , i.e. the equation

$$\Delta(E) = y^2 = t^7 - 11t^6 - t^5, \text{ for some } y, t \in \mathbb{Q}^\times$$

has solutions. Dividing out by t^4 and by change of variables we get

$$X : A^2 = t^3 - 11t^2 - t, \text{ for some } A, t \in \mathbb{Q}^\times.$$

The curve X is an elliptic curve and $X(\mathbb{Q}) \simeq \mathbb{Z}/2\mathbb{Z}$, where the rational points are 0 and $(0, 0)$. Thus $E(K) \not\supset \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/10\mathbb{Z}$.

Suppose $E(K) \supset \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/12\mathbb{Z}$. Also, $E(\mathbb{Q})$ has to either have a 4-torsion point or no 2-torsion by Lemma 8 and Corollary 12.

If $E(\mathbb{Q})$ had a 4-torsion point, then by Lemma 8, $E(\mathbb{Q}) \supset \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/4\mathbb{Z}$. We see that $E(M)$ has a 3-torsion point by Lemma 13 and hence by Lemma 5 it follows that E/\mathbb{Q} has a 3-isogeny and moreover a 4-torsion point is in the kernel of a rational 12-isogeny. It follows that E/\mathbb{Q} has a 12-isogeny and an independent 2-isogeny and now from Lemma 7 it follows that there exists an elliptic curve over with a 24-isogeny over \mathbb{Q} , which is in contradiction with Theorem 6.

If $E(\mathbb{Q})$ had trivial 2-torsion, then K/\mathbb{Q} would have to be a Galois extension for $E(K)$ to have full 2-torsion. But then by Corollary 12, $E(K)$ cannot have points of order 4, which is a contradiction.

Suppose $E(K) \supset \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/18\mathbb{Z}$. By Lemma 14, E/\mathbb{Q} has either a 9-isogeny or two independent isogenies of degree 3.

Suppose now that $E(\mathbb{Q})$ has a 2-torsion point. Then it follows, by Lemma 8, that $E(\mathbb{Q})$ has full 2-torsion. But an elliptic curve with full 2-torsion cannot have a 9-isogeny [23, Table 2.] nor 2 independent 3-isogenies [23, Proposition III.2.3]. Thus it follows that $E(\mathbb{Q})[2] = 0$ and from this that K/\mathbb{Q} is a Galois extension. Now it follows, by Lemma 19, that E/\mathbb{Q} in fact has a 9-isogeny.

By [15, Appendix], since E has a 9-isogeny, it is a twist of an elliptic curve E_0 with j -invariant as given in (15) and $\Delta(E_0) = 2^{12}3^6(t^3 - 27)$, and since E has to be a twist of E_0 , it follows that $\Delta(E) = u^{12}\Delta(E_0)$, for some $u \in \mathbb{Q}^\times$. The curve E gains full 2-torsion over a cubic field only if $\Delta(E)$ is a square, which is equivalent to

$$X : y^2 = t^3 - 27, \quad t \in \mathbb{Q} \setminus \{0, 3\}, y \in \mathbb{Q}$$

having a solution. But $X(\mathbb{Q}) = \{0, (3, 0)\}$, so there exist no such curves. \square

It is shown in Lemmas 8 and Proposition 10 that 2-Sylow subgroup of $E(K)_{tors}$ is contained in $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/8\mathbb{Z}$, in Lemma 20 that the largest power of 3 that can divide $|E(K)_{tors}|$ is 9, and in Lemmas 21 and 23 that no powers of 5, 7 and 13 (apart from 5, 7 and 13 themselves) divide $|E(K)_{tors}|$. By

[36, 37] and Lemma 22 the aforementioned primes are the only ones that can divide $|E(K)_{tors}|$.

Now Lemma 23, 24 and 27 and Proposition 25 show that $|E(K)_{tors}|$ is divisible by more than one element from the set $\{3, 5, 7, 13\}$ only for the pair (E, K) from Proposition 25. The possible combinations of 2-Sylow subgroups and p -Sylow subgroups for $p = 3, 5, 7, 13$ are dealt with in Lemmas 27 and 28 and Proposition 29.

This completes the proof that the groups that appear as torsion groups of rational elliptic curves over cubic fields are contained in the list (4). Note first that by [13, Lemma 3.2 a)], all of the groups from the list (1) appear infinitely often and the group $\mathbb{Z}/21\mathbb{Z}$ has already been dealt with in Proposition 25.

Any elliptic curve E/\mathbb{Q} with torsion isomorphic to $\mathbb{Z}/9\mathbb{Z}$ over \mathbb{Q} gains a 2-torsion point over a cubic field K defined by the cubic polynomial $f(x)$, when E is written in short Weierstrass form $E : y^2 = f(x)$. Then by Lemmas 27 and 28 it follows that $E(K)_{tors}$ does not contain $\mathbb{Z}/36\mathbb{Z}$ or $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/18\mathbb{Z}$, respectively, and therefore it follows that $E(K)_{tors} \simeq \mathbb{Z}/18\mathbb{Z}$.

It remains to prove, for each of the groups $T = \mathbb{Z}/13\mathbb{Z}, \mathbb{Z}/14\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/14\mathbb{Z}$, that there exist infinitely many elliptic curves E and cubic fields K such that $E(K)_{tors} \simeq T$.

We will deal with the groups $\mathbb{Z}/14\mathbb{Z}$ and $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/14\mathbb{Z}$ simultaneously in the following proposition.

Proposition 29. *There exists infinitely many elliptic curves E/\mathbb{Q} such that there exists a cubic field K over which $E(K)_{tors} \simeq \mathbb{Z}/14\mathbb{Z}$ and there exists infinitely many elliptic curves E/\mathbb{Q} such that there exists a cubic field K over which $E(K)_{tors} \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/14\mathbb{Z}$.*

Proof. Let E/\mathbb{Q} be an elliptic curve such that $E(\mathbb{Q})_{tors} \simeq \mathbb{Z}/7\mathbb{Z}$. By, [23, Table 3.], this curve has the model as given in (14). If E is written in short Weierstrass form $y^2 = f(x)$, then E gains a point of order 2 over the cubic field K generated by f . We will show that $E(K)_{tors} \simeq \mathbb{Z}/14\mathbb{Z}$. By Lemma 27, $E(K)$ cannot have a point of order 28, so it only remains to show that $E(K)_{tors} \not\simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/14\mathbb{Z}$

If E gained full 2-torsion over K , this would imply that

$$\Delta(E) = t^7(t-1)^7(t^3 - 8t^2 + 5t - 1)$$

is a square in \mathbb{Q} , which is equivalent to

$$X : y^2 = t(t-1)(t^3 - 8t^2 + 5t - 1),$$

having rational points such that $t \notin \{0, 1\}$. But the Jacobian J of X has rank 0 over \mathbb{Q} and it is an easy computation in Magma to show that

$$X(\mathbb{Q}) = \{\infty, (0, 0), (1, 0)\},$$

proving the claim.

To prove that there exist infinitely many curves E/\mathbb{Q} such that for each curve there exists a cubic field K such that $E(K)_{tors} \simeq \mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/14\mathbb{Z}$, we note that every elliptic curve from the infinite family of elliptic curves having

torsion $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/14\mathbb{Z}$ over a cubic field from [11, Theorem 4.2] has rational j -invariant and the cubic field over which it has $\mathbb{Z}/2\mathbb{Z} \oplus \mathbb{Z}/14\mathbb{Z}$ torsion has discriminant $(t^6 + 4t^5 + 13t^4 - 40t^3 + 19t^2 + 36t + 31)^2$, which implies that it is Galois. These are lengthy but completely straightforward calculations, and hence we leave them out.

The fact that these curves have rational j -invariant does not yet prove that the curves are rational, but just that they are quadratic twists by $\delta \in O_K$ of some rational elliptic curve. We need to prove that in fact δ is rational.

Let E_1 be one of the curves from the family [11, Theorem 4.2] and let E be a rational elliptic curve with the same j -invariant and denote $\langle \sigma \rangle = \text{Gal}(K/\mathbb{Q})$. As already noted $E_1 = E^\delta$. Let $P \in E^\delta(K)$ be a point of order 7. It follows that P^σ is a point of order 7 in $E^{\sigma(\delta)}$ and that P^{σ^2} is a point of order 7 in $E^{\sigma^2(\delta)}$.

Now we will show that in a family of quadratic twists over a cubic field K there can be only one elliptic curve with a point of order 7. Suppose that E_2/K and E_2^d/K are quadratic twists by a $d \in K^\times$ which are not K -isomorphic, and that both have a point of order 7. Then it follows that

$$E_2(K(\sqrt{d}))[7] \simeq E_2(K)[7] \oplus E_2^d(K)[7] \supset \mathbb{Z}/7\mathbb{Z} \oplus \mathbb{Z}/7\mathbb{Z},$$

or in other words E has full 7-torsion over $K(\sqrt{d})$. Since $K(\sqrt{d})$ has to contain ζ_7 it follows that $K(\sqrt{d}) = \mathbb{Q}(\zeta_7)$. But elliptic curves over $\mathbb{Q}(\zeta_7)$ cannot have full 7-torsion (see [28, Theorem.]).

Thus it follows that E^δ , $E^{\sigma(\delta)}$ and $E^{\sigma^2(\delta)}$ are all K -isomorphic which means that E^δ is a \mathbb{Q} -curve. It is known [7, Section 2.] that \mathbb{Q} -curves are either rational or defined over a $(2, \dots, 2)$ extension of \mathbb{Q} . Hence E^δ is defined over \mathbb{Q} , completing the proof. \square

Remark 30. In the proof of Proposition 29, once we have proven that E^δ , $E^{\sigma(\delta)}$ and $E^{\sigma^2(\delta)}$ are all K -isomorphic, an alternative way of proving that E^δ is rational, without using \mathbb{Q} -curves can be done in the following way.

We can see that E^δ , $E^{\sigma(\delta)}$ and $E^{\sigma^2(\delta)}$ are K -isomorphic if and only if

$$\delta\sigma(\delta), \sigma(\delta)\sigma^2(\delta) \text{ and } \delta\sigma^2(\delta)$$

are all squares in K . But since

$$N_{K/\mathbb{Q}}(\delta) = \delta\sigma(\delta)\sigma^2(\delta) = k \in \mathbb{Q},$$

it follows that

$$\delta = ka^2 \text{ for some } k \in \mathbb{Q} \text{ and } a \in K,$$

or in other words that E_1 is a rational twist of E/\mathbb{Q} , and hence can be defined over \mathbb{Q} .

Note that it is not hard to prove that there exist rational elliptic curves with non-trivial 13-torsion over cubic fields; a short search in Cremona's tables shows that 147B1 is such a curve. The hard part is proving that there are infinitely many such curves. In fact, 147B1 is the only curve with this property that we found in our (short) search.

Let $\{\pm 1\} \leq \Delta \leq (\mathbb{Z}/N\mathbb{Z})^\times$ and define the congruence subgroup

$$\Gamma_\Delta = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}) \mid a \bmod N \in \Delta, N \mid c \right\}.$$

For N prime, the modular curve $Y_\Delta(N)$ corresponding to Δ has the following moduli space interpretation: a F -rational point on $Y_\Delta(N)$ corresponds to an isomorphism class of pairs $(E, \langle P \rangle)$ of an elliptic curve E/F and a subgroup $\langle P \rangle \in E(\overline{\mathbb{Q}})$ of order N such that every $\sigma \in \mathrm{Gal}(\overline{\mathbb{Q}}/F)$ acts on $\langle P \rangle$ as multiplication by some $\alpha(\sigma) \in \Delta$. Let $X_\Delta(N)$ be the compactification of $Y_\Delta(N)$. Note that if $\Delta = (\mathbb{Z}/N\mathbb{Z})^\times$ then $X_\Delta(N) = X_0(N)$ and if $\Delta = \{\pm 1\}$ then $X_\Delta(N) = X_1(N)$ ($X_{\{\pm 1\}}$ is then defined as the quotient of \mathbb{H} by $\pm\Gamma_1(N)$, but since the action of ± 1 is trivial on \mathbb{H} , it follows that $X_1(N) = X_{\{\pm 1\}}(N)$). All intermediate curves between $X_1(N)$ and $X_0(N)$ are of the form $X_\Delta(N)$, for some Δ .

We now prove that there are in fact infinitely many rational elliptic curves with non-trivial 13-torsion over some cubic field.

Proposition 31. *There exists infinitely many elliptic curves E/\mathbb{Q} such that there exists a cubic field K such that $E(K)$ has a 13-torsion point.*

Proof. Let $\Delta = \{\pm 1, \pm 3, \pm 4\} \subset (\mathbb{Z}/13\mathbb{Z})^\times$. Then by [10, Theorem 1.1. and Table 1.], $X_\Delta(13)$ has genus 0. The existence of a \mathbb{Q} -rational cusp on $X_\Delta(13)$ now immediately shows that $X_\Delta(13)(\mathbb{Q})$ (and hence $Y_\Delta(13)(\mathbb{Q})$) has infinitely many points.

Now let $(E, \langle R \rangle)$, where E/\mathbb{Q} and $\langle R \rangle$ is a 13-cycle of E , be a point on $X_\Delta(13)(\mathbb{Q})$. If every $\sigma \in \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ acts on $\langle R \rangle$ by multiplication by an element of $(\mathbb{Z}/13\mathbb{Z})^\times$ of order 3, then it would follow that R is defined over a cubic field and we are done.

Suppose the opposite, that σ acts on $\langle R \rangle$ by multiplication as an element of $(\mathbb{Z}/13\mathbb{Z})^\times$ of order 6. It can be seen, however that when E is written in short Weierstrass form, σ actually permutes the three x -coordinates of $\pm R, \pm 3R$ and $\pm 4R$ and since $x(T) = x(-T)$ for any $T \in E(\overline{\mathbb{Q}})$, this implies that the x coordinates of the points in $\langle R \rangle$ are defined over a cubic field K . Let $F \supset K$ be the field of definition of R . If $F = K$ we are done so suppose $F = K(\sqrt{\delta})$, for some $\delta \in K$. Then $E(F)$ has a point of order 13 and since

$$E(F)[13] = E(K)[13] + E^\delta(K)[13],$$

it follows that either E or E^δ have a K -rational point of order 13. If $E(K)$ has a point of order 13 we are done. Suppose that $E^\delta(K)$ has a point of order 13. Since $F = \mathbb{Q}(\langle R \rangle)$, the field F is a Galois extension of \mathbb{Q} with $\mathrm{Gal}(F/\mathbb{Q}) \simeq \mathbb{Z}/6\mathbb{Z}$ and it follows that K is Galois over \mathbb{Q} with $\mathrm{Gal}(K/\mathbb{Q}) \simeq \mathbb{Z}/3\mathbb{Z}$. Let $\langle \tau \rangle = \mathrm{Gal}(K/\mathbb{Q})$.

Using the same argument as in the proof of Proposition 29, one can prove that $E^\delta, E^{\tau(\delta)}$ and $E^{\tau^2(\delta)}$ all have to be K -isomorphic and hence it follows that E is a \mathbb{Q} -curve and it follows that E^δ has to be defined over \mathbb{Q} .

Thus for every rational elliptic curve E represented by a point on $X_\Delta(13)$, there exists a rational twist E' such that there exists a cubic field K with the property that $E'(K)$ has a point of order 13. \square

6. SPORADIC POINTS ON $X_1(n)$

As we have seen in Proposition 25, there exists a sporadic point of degree 3 on $X_1(21)$, which is a curve of gonality 4 (the gonality of $X_1(21)$ can be deduced from [13, Theorem 2.3.] and [9, Theorem 0.1.]). This point was essentially constructed by starting with an elliptic curve E/\mathbb{Q} with a 21-isogeny and then using the division polynomial method to determine the minimal degree of a field K over which the points in the $\text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ -invariant subgroup of order 21 of some twist of E becomes K -rational.

It is a natural question to ask whether the same procedure can be used to find other sporadic points by starting with other rational elliptic curves with isogenies. We have tried this and this method gives us (only) a degree 6 point on $X_1(37)$; we describe the procedure used to find it below.

There are 2 families of twists of elliptic curves with 37-isogenies. We start with the elliptic curve $E = 1225H1$, take a short Weierstrass model

$$y^2 = x^3 - 10395x + 444150$$

of it and factor (over \mathbb{Q}) its 37-division polynomial ψ_{37} finding a degree 6 factor

$$f_6 = x^6 - 3150x^5 + 796635x^4 - 75770100x^3 + 3111596775x^2 \\ - 44606598750x - 85333003875.$$

This implies that the x -coordinate of a point of order 37 of E is defined over a sextic field F and since twisting does not change the roots of division polynomials, it follows that there exists a unique twist (over F) of E such that it has a point of order 37 over F . This can be found simply by finding over which quadratic extension $F(\sqrt{\delta})$ the points of order 37 become defined, and then the quadratic twist we are looking for is E^δ . Let w be a root of f_6 . We compute that

$$\delta = w^3 - 10395w + 444150$$

and that E^δ indeed has a point of order 37. Thus E^δ , together with a point of order 37 represents a sporadic point of degree 6 on $X_1(37)$, which has gonality 18. Note that this is the same curve which has been previously found by van Hoeij using computational methods [40].

Acknowledgements.

We thank Kęstutis Česnavičius for finding a mistake in Proposition 10 in an earlier version and for helping simplify the proofs of Propositions 9 and 10 and the anonymous referee for many suggestions that greatly improved this paper. We are also grateful to Andrew Sutherland for providing useful computational data, and to Andrej Dujella, Enrique González-Jiménez and Petra Tadić for helpful comments.
